The symposium honors Dr. Faber, a distinguished San Francisco pediatrician, Stanford emeritus professor of pediatrics, and former medical director of Chidren's Hospital at Stanford.

STANFORD--Stanford University specialists in the treatment and prevention of heart disease will be featured in a 90-minute documentary to be telecast Monday, November 19, at 8 p.m. on KQED (Channel 9).

The program, entitled "Heart Disease: The 20th Century Epidemic," is the premiere of a five-part series called "The Killers," dealing with five major causes of death in this country.

Stanford's heart transplantation program is extensively covered in the documentary. Included are the following: an interview with Dr. Eugene Dong, Jr., director of the clinical transplantation program, concerning the present and future status of heart transplants; film of a cardiac biopsy being performed on a patient; and an interview with transplant patient Ralph Trout at his Menlo Park home. Trout has survived four and one half years with his transplanted heart.

Stanford's efforts to combat heart disease through a mass media behavior change campaign in Watsonville and Gilroy will also be featured in the documentary. Dr. John Farquhar, director of the University's Heart Disease Prevention Program, will discuss the effort, and two of the television spots being utilized in the campaign will be shown.

A locally produced half-hour show, "Postscript: Bay Area," will follow the 90-minute documentary. A panel of Bay Area physicians, including Stanford's Dr. Farquhar, will discuss local heart services.

STANFORD--The Stanford University Medical Center Auxiliary surpassed the million hour mark in service to the Hospital last month. Those hours represent the equivalent of 490 people working full time for a year.

"Highly motivated and dedicated, members of the Medical Center Auxiliary have a level of skill that the Hospital could not otherwise afford to recruit," said Paul Hofmann, deputy director and administration liaison to the Auxiliary. "Their support and assistance unquestionably have played an integral role in the delivery of health care at Stanford."

The organization, formed in 1929 as the Palo Alto Hospital Auxiliary, expanded considerably when the Medical Center opened in 1959. Functioning without the assistance of even one paid employee, it now has over 1000 members, including 20 men.

Through its two gift shops, baby photo service and annual dues, the Auxiliary has raised close to $330,000 for the Hospital. Among its major gifts, have been the Hospital's blood bank, the surgery unit at Hoover Pavilion and a special room for heart transplant patients.

"Yet, the contribution of the Auxiliary is far greater than hours of dollars could possibly reflect," Hofmann points out. On behalf of the Medical Center, he has nominated the group for a National Volunteer Award, given each spring by the National Center for Volunteer Action in Washington, D.C. to an individual and a group.

"Although the Medical Center pays tribute to the accomplishments of the Auxiliary, the attitude and spirit of its members deserve broader acknowledgment," Hofmann added.

Each month, some 600 volunteers assist Medical Center staff, patients and visitors through a variety of projects. They help transport patients, deliver messages, lab specimens and reports for staff, and offer aid to relatives of patients in the intensive care unit, emergency or operating rooms.

The sum of these daily activities adds up to a contribution that is invaluable not only to the Hospital, but to the individual patients as well. As Mary Bohler, Auxiliary president, puts it:

"The lessening of tension on the face of a patient being wheeled for treatment by an Auxilian; the words of appreciation from families waiting anxiously outside surgery; the smile of a child who starts home with a puppet made by the Auxiliary as a parting gift--these are the things that make volunteering worthwhile."

While Mrs. Bohler emphasizes that it is the Auxiliary as a group which should be recognized, one member deserves special mention. She is Ann Ramsay, head of the Hoover Pavilion gift shop, who has donated over 15,000 hours to the Hospital.

STANFORD--Memorial services will be held Thu[illegible] p.m. in the First Presbyterian Church, Palo Alto for Marshall V. Virello, director of development at the School of Medicine and an associate general secretary of Stanford University.

Virello, who lived at 727 Northampton Drive, died Saturday in Los Angeles after suffering a heart attack. He and his wife Merrium had arrived at the Los Angeles Coliseum to attend the Stanford-University of Southern California football game when death came. Virello was 58.

A lifelong resident of Palo Alto, he was educated in the local schools, at San Jose State College and Stanford (class of '36). He began his career at the Palo Alto Times, where he rose to advertising manager in 1942. He was a public relations specialist with Pacific Gas and Electric Company from 1944 to 1949 and with the California Physicians Service for 11 years before accepting a post as director of public relations at the California and Hawaiian Sugar Refining Corp. Ltd.

Virello was a member of the General Secretary's Office at Stanford since 1965, and had worked extensively on foundation and major gift projects for the University and the School of Medicine.

Active in youth, church and community service, Virello had served since 1970 as president of Community Housing, Inc., a nonprofit corporation established to provide integrated low income housing for senior citizens. In the early 60's he also served on the advisory committee on public information for the City of Palo Alto.

In 1956-57, he was president of the San Francisco Advertising Club and two years later was chosen "1959 Advertising Man of the Year" in San Francisco.

He was a member of the First Presbyterian Church in Palo Alto, chairman of its building committee from 1952 to 1954, and an elder from 1958 through 1964. He was a member of the Public Relations Society of America, San Francisco Advertising Club, Commonwealth Club of California, and Press Club of San Francisco.

Survivors include his wife, Merrium, and four children: Mrs. Robert Moore of Honolulu; David, Steven and Marshall.

The family requests that memorial contributions be made to the Stanford University School of Medicine.

Tinney Funeral Chapel in Palo Alto is in charge of arrangements.

STANFORD--Stanford University physicists and heart specialists are now measuring heart blood flow and other functions through a new device which detects the heart's magnetic signals.

The new technique, still in the experimental stage, is noninvasive, safer and can be repeated more often than present methods to diagnose heart conditions.

A patient is placed in a magnetic shield which reduces magnetic interference from power lines, autos and other sources. A superconducting magnet is aimed at the heart to boost the normally weak earth's magnetic field encompassing the heart so that changes produced by blood flow can be picked up by a magnetometer, and recorded and analyzed by computer.

The device records two signals. One is the heart's magnetic field generated by its electrical activity and called the magnetocardiogram. The second signal, called magnetic susceptibility flow (MSF), is generated by the heart's contractions in the constant magnetic field created by the magnet. This signal measures the blood flow.

The magnetocardiogram is not a new concept. Its existence has been known for years through the pioneering work of Prof. David Cohen of the Massachusetts Institute of Technology.

"But the detection of magnetic signals corresponding to blood flow in the heart is new and may revolutionize diagnostic techniques in cardiology," said Dr. Donald Harrison, professor of cardiology at the Stanford University School of Medicine.

The technique is the work of a physics graduate student, John P. Wikswo, Physics Professor William F. Fairbank, and Dr. James E. Opfer. Other collaborators include Drs. Harrison and William D. Barry of the cardiology division.

"Magnetic measurements applied to the heart would be valuable for screening apparently healthy people for the presence of heart disease and also for following quantitatively a patient's disease," the researchers said.

Wikswo said the technique is expected to provide information about the heart which now can only be obtained through catheterization.

The latter is a diagnostic method by which a thin plastic tube, a catheter, is inserted into the heart chambers to take blood samples and measure pressure readings. It has its drawbacks because it is invasive, requires hospitalization, and cannot be used as often as needed for patient follow-up.

-more-

"Magnetic measurements have been an important tool in physics, but they have not been applied to medicine," Wikswo said.

"The reason," he explained, "is the small magnitude of the biologically produced magnetic signals, and the large signals present as magnetic noise in the environment."

Wikswo said these difficulties have now been overcome by the superconducting magnetometers and the construction of the special shield.

The experimental shield used in the present studies is a well 6 1/2 feet in diameter and 25 feet deep. The walls are made of special iron alloy panels backed by plastic foam to reduce vibration. Each panel can be demagnetized by an electric system. Eight feet above the bottom of the well is a fiberglass bed bolted to the floor. A superconducting magnet connected to a magnetometer is attached to a support platform above the bed and can be aimed at all desired positions to the patient's chest. The patient will enter the well at the bed level.

The superconducting magnet generates a constant magnetic field 200 times that of the earth's. The shift in position of the blood during the heart cycle causes fluctuations in the magnetic field which are detected by the magnetometer, analyzed by a computer, and presented in the form of a graph which is representative of the blood flow within the heart.

Now that these magnetic signals of blood flow have been successfully detected in healthy volunteers, the research group plans to study patients to determine the accuracy of the technique in diagnosis compared to present methods.

If these studies prove successful, a modified shield for hospital use will be built.

Details of the development of the new device will be presented November 16 at the Annual Meeting on Magnetism and Magnetic Materials in Boston. The work has been supported by a grant from the National Science Foundation's Research Applied to National Needs Program.

STANFORD--Little Marianna Smith, a 10-month-old Korean baby, is expected to have a perfectly normal and healthy life today--but without alert medical observation and some good fortune--it might not have turned out that way.

Marianna was an infant without a name, found abandoned on the streets of Seoul. She was placed with a foster family, and given the name Jo Yung Sook for the first few months of her life. After a case of measles, her future looked brighter. Last week, she was placed on an airplane bound for San Francisco International Airport to meet her new adoptive parents, Mr. and Mrs. Mike Smith of Vernal, Utah, who had flown out to meet her and take her home.

But Marianna Smith suddenly grew intensely ill during the flight from Korea. She arrived feverish and comatose. The airport doctor referred her immediately to Chope Community Hospital, where liver failure was diagnosed. Doctors recommended her transfer to Stanford University Hospital for observation and treatment.

"We had planned to take a plane out immediately to Utah," says her new mother, Joyce Smith. "If she had become ill while we were on our way home, it might have been too late."

Stanford pediatricians confirmed the diagnosis: Reyes Syndrome is an unusual disease, somewhat rare, and most often fatal.

The disease is characterized by liver failure, usually following a viral infection. The liver's function is to produce bile, convert sugars into glycogen, and store it--a function that is vital to life. Marianna was comatose and suffered severely low blood sugar--hypoglycemia.

Doctors know no "cure" for the disease except, if the patient's condition continued to deteriorate, to attempt a risky blood exchange transfusion. In Marianna's case, she improved so well with treatment of intravenous glucose and constant blood checks that such a blood exchange was not necessary.

Mike Smith, a carpenter, and his wife have a son, 6, and daughter, 9, of their own and had always wanted a larger family. "We decided we wanted to give another little child a home who's already here," says Mrs. Smith, rather than have another of their own.

However, several adoption agencies told them there would be a two-year wait, or longer. So they considered adopting a Korean baby. After several months processing with an adoption agency, word came that Jo Yung Sook would be arriving.

Mrs. Smith has stayed with her new daughter almost constantly during her illness, providing the moral support for recovery. "It's all part of the responsibility you accept when you adopt a child," says Mrs. Smith.

Financial assistance for the family came from a special fund established in the Stanford Pediatrics Department. It's made possible through donations of individuals and organizations, to support the care of children whose parents cannot meet the unexpected and costly medical bills.

Doctors expect Marianna to have perfectly normal health when fully recovered from her illness and they foresee no reoccurrence. She is expected to be released from the hospital today.

STANFORD--Stanford University Hospital physicians Tuesday (Nov. 6) warned Bay area residents to refrain from collecting and eating wild mushrooms.

Their warning came after mushroom poisoning claimed the life of Michael J. Kimble of LaHonda. He died at Stanford University Hospital Tuesday afternoon.

The 20-year-old Kimble was admitted to Stanford Sunday after sharing a meal of wild mushrooms with a friend. His companion also developed poisoning symptoms, but to a lesser degree, was treated as an outpatient and released. He is now being followed up in the outpatient clinic, doctors said.

"Mushroom poisoning sometimes resembles cholera in severity," said Dr. Peter Rudd, a resident in medicine. "The victims suffer from nausea, vomiting, abdominal pain and diarrhea.

"After a period of apparent improvement, the patients begin to show signs of liver, kidney, and central nervous system damage, with life threatening consequences."

Evidence of the effects of mushroom poison on such patients include gastrointestinal bleeding, jaundice, seizures, prostration, confusion, coma, visual disturbances and abnormal reflexes, he said.

Although the physicians are not absolutely certain which mushrooms the victims ate, the species Amanita phalloides, Amanita muscaria, and Amanita verna are among the leading causes of mushroom poisoning in the United States. They grow in abundance in the San Francisco Bay area after the fall rains and through the winter and spring.

Kimble is the first victim of mushroom poisoning at Stanford Hospital this year.

Dr. Rudd said there are drugs available which have been effective in limiting toxicity, but they must be given within eight hours after ingestion of the mushrooms.

Complicating further the problem of treatment is the toxin content which varies within species of mushrooms depending on the season, environment, and age of mushrooms, he said.

STANFORD--The effect of President Nixon's plan to cure cancer may be to slow down rather than speed up progress toward solution of the problems, a Stanford genetics professor says.

In 1970, Congress unanimously passed a resolution calling for a "national crusade" for the conquest of cancer by 1976, "as an appropriate commemorative of the 200th anniversary of our country."

Such a programmed approach to cancer research is both dangerous and shortsighted, says Leonard A. Herzenberg, genetics professor at Stanford School of Medicine, writing in the current issue of Stanford M.D., magazine of the Stanford Medical Alumni Association.

Herzenberg contends that there is much basic research to be done in many areas of biology before it is likely that we will be able to understand, prevent, and control most malignancies.

President Nixon's National Cancer Program promises to do the job by applying systems engineering managment techniques, says Herzenberg. This plan favors directed research in areas chosen by officials of the National Cancer Institute, capturing funds used previously to support traditional biomedical research.

The systems engineering approach, like that used to construct the atomic bomb and to send man to the moon, "required virtually no acquisition of new fundamental scientific knowledge; rather they demanded the practical extension and application of existing knowledge. Unfortunately, no such firm scientific base for the development of a centrally directed cancer program currently exists," says Herzenberg.

"Basic research needs considerable freedom to flourish.... It can only very broadly be directed towards an applied goal before its value as a pioneer for medical advances begins to be lost."

Basic research findings should be applied wherever they are useful, he says. "The National Cancer Program's intention to delineate narrowly the confines of cancer research is both dangerous and shortsighted," says the geneticist.

By granting large contracts for specific jobs, the program encourages groups of scientists who will direct large numbers of technicians doing rather routinized, prescribed kind of work, says Herzenberg. Graduate students and research fellows will not be drawn into this type of research, and will not be "alert to the aberrant result of chance observation that may yield a minor or major new clue to understanding cancer, or some other human disease."

Herzenberg concludes that the "centralized control of cancer research is in complete accord with the whole Nixon approach of attempting to control the entire country from the White House.

"A sweeping reversal of this whole trend" may be required to solve the cancer problem, he says.

STANFORD--A new program to explore group therapy techniques in the treatment of alcoholics has been launched by the psychiatry department of the Stanford University School of Medicine.

The program is being established after group therapy was tested with a handful of alcoholic patients over the last year. Stanford psychiatrists hope it will prove of long-term value.

"Although much has been written about the treatment of alcoholics in groups, there have been few systematic attempts to utilize the intensive group experience with these patients," said Dr. Irvin D. Yalom, professor of psychiatry and an authority on group therapy.

In such a situation, he explained, participants are stimulated by each other, develop close bonds and see the group as a powerful agent for change in their behavior.

Yalom said the Stanford groups are not intended as a substitute for Alcoholic Anonymous (AA). Rather the two approaches can complement one another.

"AA's task is to help individuals refrain from drinking," he said. "Our efforts are designed to get to the root cause of the problem--helping patients work through underlying personality conflicts which produce the fuel powering the alcoholic compulsion."

The aim, he said, is to help group members overcome feelings of self-contempt, loneliness, alienation and disengagement and to help them maintain normal social and business activities.

The program is funded by the National Institute of Drug Abuse and Alcoholism. Individuals may enroll in groups which meet once a week for an hour and a half in the afternoon or early evening. No fees are charged.

Yalom stressed there is no age limit or educational level for the patients admitted. And names are kept confidential.

The Stanford psychiatrist prefers groups to be small. "Those consisting of approximately seven members are ideal to permit considerable face-to-face interaction," he said -more-

The groups meet under the guidance of faculty and experienced therapists. There are three therapists on the project, Stephanie Brown, Sidney Block and Yalom.

"Before therapy begins," said Yalom, "patients are interviewed to determine their suitability and are prepared for the experience that lies ahead.

"We suggest they may find the experience discouraging or even frustrating at first, but urge them to make a commitment for at least a dozen sessions before attempting to judge whether the groups will be useful to them."

"Patients are also asked to delineate their goals in therapy," he said.

To provide a clear view of how the patients function, the group sessions are videotaped. On subsequent sessions, the tapes are played back. "Videotape playback has the potential of reducing anxiety. It is a constructive experience for some to observe themselves," he said.

Another approach used to help members observe and understand their behavior is by discussing summaries written by the therapists of each session.

"Our written formulations have underscored the relevance and importance of honest feedback," said Yalom. "We want to eliminate the stereotype of the mysterious therapist who never explains things to patients."

These discussions, the psychiatrist said, help patients assume the self-reflective position which is so essential in group therapy.

"It would be premature to comment on the results of each patient," said Yalom. "This type of group therapy has ambitious goals and is a long process. But the endeavor so far to establish a working therapy group made up of alcoholics has been successful."

Individuals who wish to participate in the research may call 321-1200, Ext. 3652. ###

STANFORD--A course in operating room techniques offered by Stanford University Hospital has been accredited as a postgraduate course for nurses by DeAnza College. Effective winter quarter, which begins January 2, 1974, the six-month course will be worth 34 academic units.

The program was initiated by Stanford in 1968 to educate more registered nurses in the specialized skills of the operating room. Since then, nurses from all over the country and as far away as England and Nigeria have come to the Hospital for training.

Instruction by nursing and medical personnel at Stanford includes classroom lectures and supervised clinical experience in the principles of asepsis and various surgical procedures. Students receive a monthly stipend.

STANFORD--The Professional Women of the Stanford Medical School (PWSMS) have voted to remove all restrictions on membership in the organization. Any person, male or female, who supports the group's purpose of "promoting development of opportunities for women equal to those of men in the medical sciences" is eligible to join.

Founded in 1969, PWSMS was previously open to women at the Medical School studying for or holding doctoral degrees. A new amendment to the organization's constitution was passed at the annual October, 1973 meeting to eliminate all restrictions based on training, position, geographic location and sex.

The group will still focus on women in careers related to medicine, but it now intends to include the problems faced by social workers, nurses, dieticians, technicians and other health care professionals. New members are welcome from both Stanford and the community, according to PWSMS officers. Those nterested should contact membership secretary Dr. Netta Grandstaff of the Department of Family, Community and Preventive Medicine.

Since its inception, PWSMS has been involved in several issues affecting women at Stanford Medical School. At the suggestion of the group, a McCormick Memorial Lectureship has been established in the School of Medicine to bring outstanding women physicians and scientists to the Medical School. Funds will be provided from the $5 million bequest of Katharine McCormick to the Medical School in 1969 "for the encouragement and assistance of women in...medicine." Speakers will be selected by a committee headed by Dr. Rose Payne, professor of medicine.

PWSMS members have also participated on the Joint Committee on the Status and Tenure of Women, set up by the Medical School in 1970 to develop ways of increasing the number of women hired and promoted to faculty positions. Others PWSMS proposals on behalf of women include establishment of a separate academic ladder for research personnel, many of whom are women, to bridge the gap between research associate and an independent senior scientist; and creation of an Office of Women's Affairs with part of the McCormick bequest to help improve the career opportunities for women at the Medical School.

Chairwoman of PWSMS for 1973-74 is Dr. Helene Rauch of medical microbiology. Other members of the council are: Dr. Sonia Baur, medicine; Sally Dorfman, medical student; Sara Gerling, graduate student; Dr. Dora Goldstein, pharmacology; Dr. Netta Grandstaff, family, community and preventive medicine; Rose Grobstein, medicine; Dr. Dorothy Huntington, surgery; Leona McGann, family, community and eventive medicine; Dr. Myrna Miller, psychiatry; Drs. Lois O'Brien and Ann Taylor, medicine.

Two of the council members, Drs. Baur and Goldstein, along with Dr. Marion Smith of neurology, were among the four Medical School representatives elected to the University Academic Senate last spring.

STANFORD--Dr. Bruno Bettelheim, world-renowned children's psychologist and psychcanalyst will be visiting professor of psychiatry at the Stanford University School of Medicine.

The appointment was announced by Dr. Albert Stunkard, chairman of psychiatry at Stanford.

Dr. Bettelheim is Stella M. Rowley distinguished service professor emeritus of education, psychology and psychiatry at the University of Chicago. For the past 29 years he has been director of the Orthogenic School, the University's residential treatment center for severely emotionally disturbed children. He is world famous for his work in rehabilitation of autistic children.

His primary responsibility at Stanford will be continuing education programs for the Medical Center's clinical faculty He also plans to teach in the School of Education at Stanford during the summer quarter.

Early in his work in Europe, Dr. Bettelheim and his wife took into their home a seven-year-old istic American girl, who had been diagnosed as hopelessly feebleminded. This was a decade before the autistic child was described in scientific literature. He worked with her until Hitler annexed Austria in 1938, at which time his wife and his "patient" left for America. Dr. Bettelheim, who had received his Ph.D. just before the German Anschluss, was imprisoned by the Nazis, whom he had long opposed. He was in the Dachau and Buchenwald concentration camps.

"It wasn't like with some of today's young people who think you can be a great revolutionary without paying for it," he has said. His experiences during this time provided him with materials for two books: Individual and Mass Behavior in Extreme Situations, and The Informed Heart.

With his release in 1939, he came to the U.S., and became research associate with the Progressive Education Association at the University of Chicago.

He became an American citizen, began his association with the Sonia Shankman Orthogenic School, and concurrently became professor of educational psychology at the University of Chicago.

Dr. Bettelheim has published widely both in professional journals, and in many popular magazines. He has written about the alienation in modern society, the role of women, sex and violence, education of gifted, and of emotionally and culturally deprived children, academic discontent, and many other cs.

Some of his books, such as The Empty Fortress, Love is Not Enough, and Truants From Life, describe the work of the Orthogenic School in rehabilitating severely disturbed youngsters.

-more-

Others are based on his many years of helping parents of normal children with the problems of childrearing. His well-known Dialogues with Mothers, and others have been translated into all major languages.

His most recent book, Children of the Dream, discusses communal childrearing in the Israeli Kibbutzim and its implications for American education. Other books include Symbolic Wounds and Social Change and Prejudice.

A new book will be published in early 1974, dealing with what mental institutions should be like, a guide to what patients should expect.

Dr. Bettelheim is a founding member of the National Academy of Education, a fellow of the American Academy of Arts and Sciences, a fellow and diplomat of the American Psychological Association, and a fellow of the Orthopsychiatric Association.

He and his wife will make their home in Portola Valley.

STANFORD--A new clinic for the diagnosis and treatment of patients with multiple sclerosis has been established by the Department of Neurology at Stanford University Medical Center.

The clinic provides complete neurological evaluations and diagnostic studies for patients with suspected or known multiple sclerosis, said Dr. David Prince, department chairman. Patients are preferably accepted on a referral basis.

Multiple sclerosis (MS) is a disease of the central nervous system in which nerves lose their insulation--a coating called myelin. This may result in a variety of symptoms including weakness, lack of coordination, and disturbances of speech and vision.

The cause of the disease is unknown, although much progress is being made toward understanding the possible basic mechanisms which produce its symptoms, according to Dr. Frederick Seil, clinic director.

Dr. Seil emphasized that there is no effective treatment for MS at present. He and his colleagues are actively pursuing research focusing on improving the understanding, diagnosis and management of demyelinating diseases, particularly multiple sclerosis.

STANFORD--John J. Schwartz, special assistant to Stanford University President Richard W. Lyman, has been appointed counsel for medical affairs at the University Medical Center.

The move was announced Wednesday, December 19, by Dr. Clayton Rich, vice-president for medical affairs and dean of the School of Medicine.

Schwartz's appointment is part of a reorganization of legal services within the University. Previously, the Medical Center's legal affairs were handled on a part-time basis by Schwartz and attorneys Cassius L. Kirk and Merel Glaubiger of the Business and Finance Office.

Kirk will return full-time to the Business and Finance Office. Mrs. Glaubiger will become associate counsel for medical affairs.

Schwartz, 39, is a native of White Plains, New York, and a graduate of Cornell University (1955). He received his law degree from Harvard in 1958 and obtained a Ph.D. in physics from the University of Rochester in 1965.

He practiced law in Phoenix, Arizona and taught physics at the University of Rochester before coming to Stanford in 1969 as assistant professor of physics. He has served as special assistant to President Lyman since 1970.

Schwartz, his wife and four children live at Stanford.

"Over the past several months, John has been invaluable in dealing with a wide range of issues in the Medical Center which involve questions of a legal nature," Dr. Rich said. "His appointment will achieve needed coordination of legal services for the Hospital, Clinics and Medical School."

STANFORD--A new rehabilitation program for heart attack victims has been launched at Stanford University Hospital.

The program, begun December 1, consists of exercise testing and training, physical therapy, and psychological and dietary counseling.

Its overall goal, said Dr. Robert F. DeBusk, program director, is "to get heart patients back on their feet and back on the job sooner--and safely."

Two major functions of the program are the determination of how much exercise each patient should undertake and the development of a "prescription" for regulating home activity, said DeBusk, assistant professor of cardiology at Stanford.

"Many patients go home and feel very threatened without doctors and nurses around," he said. "They lack confidence in themselves and don't know how much they should do.

"This program enables us to tell good risk patients to be more active and less of an invalid. They can go home assured of just what they can and can't do."

DeBusk said that the Stanford program will also attempt to meet the patients' psychological needs. Eliminating the uncertainty about physical exertion is an important first step, he said.

Additionally, a staff psychologist will provide counseling in overcoming depression related to serious illness, as well as encouragement in making recommended behavioral changes such as weight reduction.

"Depression is a normal part of the patient's reaction to a life-threatening illness," DeBusk said. "The concern is to keep him from looking at himself as a sick person, instead of someone who will recover and maximize his own functional capability."

The program begins when the patient is still in the hospital following a heart attack. Prior to discharge, approximately three weeks after the attack, he is given a carefully-monitored minimum cardiac stress test. The test simulates stress the patient would have at home in activities such as climbing stairs.

In developing a home activities plan, test results are considered along with 10 or 24 hour tape recordings of the patient's heart action made while he is ambulatory.

Throughout the first 12 weeks after the heart attack, the patient follows a program of increasing physical activity at home. Follow-up testing is conducted at two to three week intervals to determine how much his capability increases.

-more-

After 12 weeks, the patient will be encouraged to join a long-term exercise program, such as the cardiac rehabilitation program directed by Dr. Gary Fry of the Palo Alto Medical Clinic.

Patients can be admitted to the Stanford program upon referral by their physician. All data obtained in the program will be made available to the referring physician. Costs are billed to the patient's health insurance carrier.

DeBusk, who feels "the application of cardiac rehabilitation up to now has lagged behind that of heart surgery," hopes the program will show that rehabilitation training can be effective in prolonging the lives of patients with heart disease.

"I don't think anyone would dispute the fact that the quality of life is improved through rehabilitation programs," he said, "But we need data to establish the efficacy of rehabilitation in terms of preventing sudden death and prolonging life."

Though the initial focus of the program will be on patients who have suffered heart attacks, he hopes to extend it to those who have undergone coronary bypass surgery and those with stable angina pectoris or chest pain.

"In Santa Clara County alone, there are tens of thousands of people who should be given cardiac stress tests," DeBusk said. "This figure includes survivors of heart attacks, patients who have had heart surgery, and individuals with noticeable symptoms, as well as others who are apparently normal but have risk factors of coronary heart disease.

"Many can be put on an exercise program to help determine whether it can prolong life not only for heart attack victims, but for others in the early stages of heart disease as well."

Co-director of the Stanford program is exercise physiologist Dr. William Haskell. The staff also includes a nurse, psychologist, and Stanford Hospital dieticians and physical therapists.

STANFORD--A cell separating instrument developed at Stanford University School of Medicine will soon be employed as an important research tool in laboratories all over the world.

The first two commercial versions of the cell separator, built by the Becton-Dickinson Electronics Laboratory of Mountain View, California, went into operation this month at Stanford and the National Cancer Institute. Early in 1974, another group of instruments will be produced for additional research teams in Europe and the United States.

Scientists believe that the cell separator may open the door to a better understanding of the body's immune or defense system, as well as new research and clinical study of diseases in man.

It is the first device which enables researchers to take rare cells from the general cell population for inspection and experimentation. Cells are observed individually and separated on the basis of their fluorescence and light-scattering ability.

Several thousand cells can be processed per second, and populations in fractions as small as one in 1 000 can be identified.

Previous bulk methods (utilizing a centrifuge, separation columns, or electrophoresis) allow sorting of large numbers of cells, but produce only limited separation of functionally different types.

The cell separator was developed by a Stanford team which includes Dr. Leonard A. Herzenberg, professor of genetics; engineers Richard G. Sweet and William A. Bonner; and research associate H. Russel Hulett.

One of the most important applications of the separator, Herzenberg said, is in the study of the body's cancer and infection-fighting immune system.

"We hope to determine the chemical and biological characteristics of the different cells involved," he said, "as well as the specific functional roles they play.

"Increasing our knowledge about the immune system could lead to better understanding and hopefully prevention of organ transplant rejection. It may also lead to more effective treatment of diseases such as leukemia and hemophilia."

At Stanford, a series of experiments focusing on the roles of specific cell types in the immune process has begun.

The instrument works as follows: cells suspended in the central stream of a very small liquid jet are observed individually as they pass through two laser beams. The jet is later broken into uniform droplets. The droplets containing the desired calls are charged electrically and then deflected in an electric field.

Two characteristics serve as the basis for separation: fluorescence, which can be used to detect functional differences after reacting the cells with fluorescent-labelled proteins, and light-scattering ability, which is a function of particle size and internal structure.

Work on the development of the cell separator began at Stanford seven years ago with grant support from the National Institute of General Medical Sciences.

Early in 1972, the investigators received a contract from the National Cancer Institute to build two prototype instruments. The engineering and fabrication were subcontracted to Becton-Dickinson. The Stanford team provided the original machine as a model, and supplied design concepts and techniques.

The goal was to come up with a standardized version which could be made available to other researchers.

"The new machine is more sophisticated than the original," Sweet said. "The operation and maintenance now have been simplified enough so that a non-engineer can run it." Mailed, Monday, Dec. 17, 1973

STANFORD--Dr. David A. Prince of Palo Alto has been elected president of the American Epilepsy Society.

Prince, 40, is professor and chairman of the Department of Neurology at the Stanford University School of Medicine, and neurologist-in-chief at Stanford Hospital.

His election was announced this week in New York at the society's annual meeting.

Prince and his associates have pioneered in studies of single nerve cells responsible for abnormal electrical discharges that characterize epilepsy in animals and man.

The society is a nonprofit organization made up of more than 600 physicians and scientists. Its purpose is to foster efforts in clinical care and research in epilepsy.

Prince is a medical graduate of the University of Pennsylvania. In 1971 he received a John Simon Guggenheim Memorial Foundation Award for his research in epilepsy.

STANFORD--Stanford University Medical Center has launched two new programs as part of a continuing energy conservation effort.

A free bus service to transport employees between the Southern Pacific Palo Alto Train Station and the Medical Center will be initiated January 2, 1974. Additionally, employees who form car pools of four or more persons will receive free parking privileges in the pay parking lot near the Center whenever three or more riders are in the car.

"Our goal is to reduce energy consumption and relieve the somewhat congested parking conditions at the Medical Center," said Peter Carpenter, assistant vice-president for medical affairs. "We hope these programs will motivate employees to form car pools and ride commuter trains and buses."

The bus service will begin with two runs each morning and late afternoon between the S.P. station and Medical Center. A rented 38-passenger bus will leave the station at 7:45 and 8:10 a.m. Monday through Friday; it will leave the Medical Center at 5:00 and 5:45 p.m.

The runs coincide as closely as possible with employee work shifts and scheduled trains and buses which serve the S.P. station and the nearby Greyhound Bus Terminal. If the demand exists, the number of runs and the size of the buses will be increased, Carpenter said.

EDITORS: Copies of Stanford M.D. available on request if not included with release.

STANFORD--The Tuskegee syphilis study, involving 399 black men whose infections were allegedly left untreated since 1932, was not a "medical atrocity" as it was publicized in the press, says a Stanford professor.

There is no evidence that treatment was deliberately withheld from the participants, says Dr. Charles W. Barnett, emeritus professor of medicine at Stanford University Medical School, who has made a study of the controversial project.

Lack of treatment was not contrived by the U.S. Public Health Service, but was an established fact before the study began, he maintains.

He terms the study "a fully justified investigation. It stood a fair chance of adding immensely to our meager knowledge of the natural history of the disease, without endangering the lives of the syphilis subjects," Dr. Barnett writes in the current issue of Stanford M.D., a magazine of the Stanford Medical Alumni Association.

"The study proceeded peacefully, with numerous publications...and received no attention outside the medical profession until it was discovered by the Associated Press in 1971. It was then publicized widely as a horrible medical atrocity against a poor, suppressed black minority. It was alleged that the odious physicians...had callously withheld from them life-saving therapy without telling them that they had a horrible disease for which there was a readily available and infallible treatment," writes Dr. Barnett.

It was assumed that therapy, particularly with penicillin, results in a complete cure. "Unfortunately, this idea has rubbed off onto some in the medical profession," says Dr. Barnett. "The fact is that no amount of any kind of treatment will always prevent the development of later manifestations of the disease."

He points out that "there is little reason to suppose that treatment of latent syphilis with penicillin would have changed the lives of the subjects."

In 1973 an Ad Hoc Advisory Panel of the Department of Health, Education and Welfare investigating the study issued its final report. It concluded that the study was never justified because it did not obtain informed consent from the participants.

The Panel said the study should have been ended when penicillin became available in 1952. And it called for a complete overhauling of the current system for protection of human subjects.

-more-

Dr. Barnett disputes these conclusions, and says the medical profession should protest unjustified charges. "It is highly probable that the untreated blacks in the Tuskegee study did not have treatment withheld from them deliberately, and their failure to get therapy was by their own choice." In fact, he says, many of the originally untreated subjects did get treatment during the course of the study.

Treatment at the time consisted of weekly doses of arsphenamine, alternating with weekly injections of mercury or bismuth for up to two years. Reactions were frequently painful and severe.

"Latent syphilitics have no infection they are trying to clear up. When treatment makes them sick, and they feel well without it, they have doubts about the wisdom of continuing it," writes Dr. Barnett.

The treatment of advanced syphilis by drug therapy was often discouraging to both physician and patient, Barnett points out. Frequently one started with a well patient with a positive test, gave a two-year series of expensive and painful injections that often made the patient sick, and wound up with a well patient with a positive test. Sometimes it seems that the black patients who refused treatment were smarter than the doctors who prescribed it, says Barnett.

He notes that press reports emphasized that the untreated group could transmit the infection to others, but if treated, they could not.

"This is complete nonsense," he says. Syphilis is transmissible only in the first few years of the disease, probably never after four years and only very rarely during the fourth year. Participants selected for the study all had their disease for at least three years or longer.

It seems that syphilis produces some change in the bodily defense system that makes the infected person more susceptible to disease, like cardiovascular disease, that is not directly related to the infection.

"A great deal of effort has been expended over many years to find the effect of therapy on the progress of syphilitic disease itself," says Dr. Barnett, "but nothing at all is known about the effect of antisyphilitic therapy upon this vague nonsyphilitic threat to life and health."

He says that a shortcoming of the study was that it did not include a control group of treated patients. If it had, information about the long-range effects of the disease might have been obtained.

Barnett has been a member of the Stanford faculty since 1927. He was director of the syphilis clinic at Stanford in San Francisco for nearly 30 years, and he became director of the general medical clinic when the medical school moved to Palo Alto.

STANFORD--A new educational program focusing on the rehabilitation of cancer patients has been launched by the Division of Physical Therapy at Stanford University Medical School.

Supported by a two-year grant of $231,260 from the National Cancer Institute, the program enables Stanford physical therapy students to work with patients facing the difficult adjustments to life-threatening illness and disability.

The training effort stresses technical knowledge and skills required to treat cancer patients, and especially the social and psychological ramifications of the disease, said Helen Blood, head of the Division of Physical Therapy.

"Unfortunately, many health professionals tend to avoid working with cancer patients," Miss Blood said.

"Those who do get involved often lack specific knowledge or have a pessimistic and fatalistic attitude which can affect the patients. We hope to do something about these problems."

Under the new training plan, Stanford's 45 physical therapy students are involved in cancer rehabilitation throughout their two-year Master's program. The first-year curriculum now includes observation and supervised treatment of patients, as well as classroom instruction in basic cancer terminology and therapy, up-to-date rehabilitation techniques, and psycho-social aspects of working with cancer patients and their families.

In their second year, students may take an advanced course in which they assume increased responsibility for the rehabilitation of two or three patients and their families. Other second-year courses have been modified to place added emphasis on cancer rehabilitation.

A major goal of the Stanford effort, Miss Blood said, is to develop a model training program which can be adopted in whole or in part by other physical therapy schools.

With this in mind, Stanford will sponsor one-week summer workshops this year and again in 1975. Participants will include faculty members and clinicians from the 10 physical therapy schools in the western United States; in 1975, practitioners from the Bay Area will also attend.

Workshop participants will help evaluate the cancer program and its application to physical therapy education and practice, Miss Blood noted. Evaluations will also be obtained from Stanford trainees and the patients they have treated.

Principal investigator for the program is Barbara Kent, assistant professor of physical therapy. Other Stanford faculty members involved in the program include Carolyn Houser, Kay Shepard, John E. Bell, and Linda Van Hoesen.

STANFORD--"The Values of Children" will be the topic of the second annual Alfred E. Weisz Memorial Lecture on Tuesday, January 29 at 8 p.m. in Bishop Auditorium on the Stanford campus. The lecture is open to the medical community, students and the public.

Dr. James T. Fawcett will be the speaker. He is assistant director of the East-West Population Institute in Honolulu, Hawaii, and associate professor of psychology at the University of Hawaii.

Dr. Fawcett has done extensive cross-cultural studies of the different reasons why people have children. He has been associated with the Population Council for several years, and worked on population problems in Thailand for four years.

He is the author of several books, including Psychology and Population: Behaviorial Research Issues in Fertility and Family Planning, published in 1970. He also edited a collection of essays of psychological perspectives on population in 1973.

Dr. Fawcett received his Ph.D. in psychology at the University of California--Berkeley.

The Weisz Memorial Lecture was established in 1973 to honor the memory of Dr. Alfred E. Weisz, assistant professor of psychiatry at the Stanford University School of Medicine, who died of cancer in 1970.

The Weisz lectures emphasize the psychological aspects of population, according to Dr. Warren B. Miller, assistant professor of psychiatry at Stanford, who is coordinator for the lecture.

STANFORD--"Overweight and Obesity" will be the topic of Dr. Albert J. Stunkard, professor and chairman of the Department of Psychiatry, at the fourth Progress in Medicine lecture on Wednesday, January 30, at 8 p.m. in Memorial Auditorium.

The series of weekly lectures are presented by the Stanford University Medical School as a public service to the community, and are free of charge.

Dr. Stunkard is a nationally known expert in human eating disorders, including both obesity and pathological under-eating. He identified the "night eating syndrome," a pattern of food intake which characterizes patients who are resistant to weight reduction regimens. He also published the early observations of "dieting depression," a psychological response in some individuals attempting to lose weight.

Dr. Stunkard is a medical graduate of Columbia University, and former head of the Department of Psychiatry at the University of Pennsylvania. He is recipient of the American Psychiatric Association's Hofheimer Prize for research.

STANFORD--Because of record attendance the Progress in Medicine lectures featuring recent advances in psychiatry have been moved from the Medical Center to Memorial Auditorium, the Stanford University School of Medicine announced Friday (Jan. 18).

Dr. David Hamburg, Reed-Hodgson professor in human biology, will present an illustrated lecture on "The Relevance of Primate Research for Psychiatric Disorders" Wednesday (Jan. 23) at 8 p.m.

He is a leading authority in the study of hormonal responses to psychological stress and past chairman of the Department of Psychiatry.

Dr. Hamburg has been instrumental in developing the Laboratory of Stress and Conflict at Stanford, and also directs research on chimpanzees at Stanford's primate facility and in Africa. He is a 1947 graduate of the Indiana University School of Medicine, and received his professional training at Michael Reese Hospital in Chicago.

The other scheduled lectures to be held at Memorial Auditorium are:

January 30: "Overweight and Obesity," by Dr. Albert J. Stunkard, professor and chairman of the Department of Psychiatry.

February 6: "Sleep: What Can Go Wrong with It and What to Do When It Happens," by Dr. William C. Dement, professor of psychiatry.

ADVANCE FOR AM RELEASE SUNDAY, JANUARY 20, 1974

STANFORD--Will my child walk? When? These are the questions most frequently asked by parents whose children have cerebral palsy or slow development.

A Stanford University orthopedic surgeon has devised a simple and effective method to help answer those parents.

The test, based on the presence or absence of seven reflex responses, can predict with close to 95 percent accuracy if a child with cerebral palsy or delayed motor development will walk.

It was developed by Dr. Eugene E. Bleck, chief of the orthopedic rehabilitation service of Children's Hospital at Stanford. He used the method for prognosis in 73 nonambulatory children followed from 1958 to 1973

Bleck reported the results of his research today (Sunday, January 20, 1972) at the annual meeting of the American Academy of Orthopedic Surgeons in Dallas, Texas.

Cerebral palsy, a movement and coordination disorder caused by injury to the immature brain, affects some 750,000 in the United States. Among other things, it may result in impaired use of arms and legs.

Predicting whether or not a child will be able to walk can affect parental attitudes, clinical management and surgical decisions, according to Bleck.

Parents who know their children have a poor prognosis for walking will not have unreasonable expectations, he explained. Different goals can then be set up to include such needs as feeding, dressing and wheelchair manipulation.

Watching the painstakingly slow progress of children learning to walk can be frustrating for therapists and heartbreaking for parents. In the study, Bleck found that when children had a favorable prognosis for walking, but seemed to make little progress, both therapists and parents were more relaxed and patient.

Some children require orthopedic surgery to improve their function by restoring muscle balance. Bleck recommends postponing such surgery until a walking pattern has been established because better results have been obtained. If however, there is a structural change in the limb joints, surgery is indicated. A prognosis for walking can help surgeons decide when to perform surgery.

The 73 children were first examined when they were between ten months and four and one half years old, and then re-examined at regular intervals.

Seven automatic reflexes were tested, including the parachute reaction, which normally involves extending the arms when suddenly lowered, as if to break a fall. Children were graded one point for each abnormal reflex. A score of zero was a good prognosis for walking, and a score of one was guarded. A score totaling two or more was poor.

-more-

By the time they were seven, 54 of the children studied could walk at least 50 feet without falling. These included all but three of the 49 who scored zero, and seven of those with a score of one. One child with a score of two also walked at the age of seven.

Forty-one children were able to walk without crutches, although with some lack of coordination. These children could also climb stairs and demonstrated ability to run. None of the children regressed to not walking.

There was some correlation between the type of cerebral palsy and the age of walking. Those with some paralysis on one side only could walk at the earliest age (about two years old). Thirty-six of the children in the study were walking by age four. Practically all children who are going to walk will do so by the age of seven years, said Bleck.

In the past, two infant reflexes were used to predict locomotion, but they were not very dependable, Bleck noted. He said the tests developed in this study are more reliable. Because some of the reflex actions do not appear immediately after birth, he suggested waiting until children are at least one year old before making any firm walking prognosis.

ADVANCE FOR PM RELEASE TUESDAY, JANUARY 22, 1974

STANFORD--The knee is the most common target of injury in automobile accidents when the front seat occupants are not wearing seat belts, Stanford University researchers reported Tuesday (Jan. 22).

After a collision, the unrestrained occupant is driven forward, and the knee strikes the dashboard in a "second collision."

"The extremities might be considered then the first line of defense against the frontal impact," said Dr. Donald A. Nagel, associate professor and head of the Division of Orthopedic Surgery.

Dr. Nagel presented his findings at the meeting of the American Academy of Orthopedic Surgeons in Dallas, Texas. The study, funded in part by the National Highway Traffic Safety Administration, was done in association with Dr. Davis S. Burton, an orthopedic surgeon, and Dr. John Manning, assistant professor of mechanical engineering.

The group studied 153 persons injured in California accidents. Fifty-seven sustained a total of 80 injuries to their knees. Sixty-nine of the injuries were caused from contact with the dashboard.

Dr. Nagel has labeled these injuries "the dashboard knee."

Injuries usually correlated with the severity of the accident, he told the academy. Injuries were mild in lighter accidents and severe in major accidents. In some major accidents, persons wearing seat belts got off with only minor injuries to the knee.

If the knee should strike a protruding knob or sharp edge, the force of deceleration is concentrated in a small area, and a severe laceration or fractured knee cap can result, Dr. Nagel said.

"When the point of contact was smoothly contoured sheet metal, the dashboard usually deformed and did not cause major injury to the knee," he reported. "But trapping of the leg below the dashboard with overstraightening of the knee will tear capsules and ligaments."

In the Stanford study, doctors and engineers investigated 74 accidents and reconstructed each one to determine occupant motion and correlate this information with the occupant injuries.

"It is our hope," said Dr. Nagel, "that with better understanding of the mechanism of injury of the dashboard knee, we will be better prepared to diagnose and treat the various injuries. The automotive engineers will also be able to redesign automobile interiors so that there will be fewer injuries."

In California alone a total of 252,429 people were injured in auto accidents in 1972.

STANFORD--Ten young scientists pursuing careers in teaching and research at Stanford University School of Medicine have been named Andrew W. Mellon Fellows.

They will be supported in part over the next three years by a $325,000 award to Stanford by The Andrew W. Mellon Foundation of New York "to assist young postdoctoral scholars of exceptional promise and ability."

The fellows were announced recently by Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine.

According to the Mellon Foundation, "The chief purpose of the grants is to help minimize the loss to medical education and to research in the basic medical sciences which is certain to occur if individuals...are forced by lack of support to turn to other careers."

Stanford is one of 15 private medical schools to receive such funds under the newly established Mellon Foundation program. With the award, the School of Medicine can continue to contribute to the professional development of some of its most promising young teacher-scientists, said Dr. Rich.

Those designated fellows are:

. Dr. Douglas L. Brutlag, who will join the Department of Biochemistry in September, 1974. He is presently with the Commonwealth Scientific and Industrial Organization in Canberra, Australia, where he is studying the DNA--the substance that determines heredity--of the fruit fly.

. Dr. John R. Daniels, assistant professor of medicine in the Division of Oncology. He is conducting clinical studies in cancer chemotherapy and research on the chemistry of collagen--a fibrous protein--in kidney, lung and blood vessel membranes.

. Dr. Henry F. Epstein, assistant professor of pharmacology and a fellow of the National Genetics Foundation for 1973-74. His work on the genetic and molecular basis of muscle development in nematode worms may lead to better understanding of inherited nerve and muscle disease. -more-

. Dr. Errol C. Friedberg, assistant professor of pathology, whose research concerns the repair mechanisms of DNA.

. Dr. Michael L. Goris, assistant professor of radiology in the Division of Nuclear Medicine. He is applying mathematics and computer science to diagnostic procedures using radioactive tracers.

. Dr. Randall H. Griepp, assistant professor of surgery in the Division of Cardiovascular Surgery. A member of the Stanford heart transplant team, he heads the cardiovascular research laboratory which is doing immunological studies on heart transplantation. He is also doing animal research on cooling down the body to stop circulation while surgery is performed.

. Dr. S. David Holtzman, assistant professor of neurology and head of the Division of Pediatric Neurology. His interest is the biochemistry of the developing brain and the effects of fetal and neonatal disease on its maturation.

. Dr. John D. Johnson, assistant professor of pediatrics. Also assistant director of the nurseries, he is interested in the relation of bilirubin (bile) metabolism to jaundice in newborn infants.

. Dr. Allen K. Ream, assistant professor of anesthesia, who is using computer techniques to monitor patient physiology.

. Dr. William T. Wickner, fellow in the Department of Biochemistry. He is studying the enzymes involved in DNA synthesis in the Phi X174 phage, a dwarf virus considered one of the simpler forms of life.

STANFORD--A five-year federal grant of $2.75 million has been awarded to Stanford University School of Medicine to establish the first shared national computer facility for medical research.

The computer, expected to serve as an important research tool in problem solving and analyzing data, will be used by medical investigators throughout the country on a time shared basis.

Funded by the Division of Research Resources of the National Institutes of Health (NIH), the facility will be known as the SUMEX--Stanford University Medical Experimental Computer--and directed by Dr. Joshua Lederberg, professor and chairman of the Department of Genetics at Stanford.

The two main objectives of the SUMEX program, Lederberg said, are the development (with the NIH Biotechnology Resources Branch) of the relatively new concept of national shared resources, and the further exploration of computer science applications in medicine.

Initially, SUMEX will consist of a powerful PDP-10 computer, scheduled to be delivered and installed in April. The computer will be available to approved users through a computer-communication network.

The primary focus of the SUMEX project, Lederberg said, will be on applications of artificial intelligence in medicine (AIM). A national AIM coordinating group, now being organized, will advise on the management of the facility and review applications for eligibility to use it.

Artificial intelligence is a part of computer science concerned with the symbol-manipulation processes that produce intelligent action. Rather than employing the digital computer as merely a number calculator, scientists in this field utilize the computer to reach decisions and solve problems through symbolic analysis and reasoning.

SUMEX will be staffed by a group of scientists experienced in artificial intelligence techniques, Lederberg said.

Core research efforts at Stanford will include on-going interdisciplinary projects involving Drs. Lederberg, Edward Feigenbaum (computer science) and Carl Djerassi (chemistry). They are applying artificial intelligence techniques to the study of unknown organic compounds. The computer analyzes data obtained from instruments such as mass spectrometers in an attempt to determine molecular structure.

A new project, in collaboration with Dr. Stephen Freer of the University of California, seeks to infer protein structure from data obtained by an x-ray crystallograph.

Other scientists who have been identified as initial users of the computer resource include Dr. Saul Amarel of Rutgers University, who is directing several projects in artificial intelligence in biomedicine, and Drs. Stanley Cohen (pharmacology), Stanton Axline (infectious diseases) and Kenneth Colby (computer science) of Stanford.

Cohen and Axline are utilizing the computer to help plan strategy for the treatment of infectious diseases.

STANFORD--Dr. Ulf S. von Euler, a Swedish neurophysiologist who won the 1970 Nobel Prize in medicine and physiology for his studies of the chemistry of the central nervous system, will give the first Windsor Cutting Lecture at the Stanford University School of Medicine Monday (January 21).

He will speak on "Some Problems Related to Adrenergic Neurotransmission" at 4:15 p.m. in Room M106 of the Medical School. The lecture is open to the medical community and the public.

Dr. von Euler is professor of physiology emeritus at the Karolinska Institute in Stockholm. He studied how nerve impulses are transmitted chemically across minute insulating gaps--synapses--which separate nerve from nerve or nerve from muscle. In 1947 he demonstrated that the transmitter substance which diffuses from the ends of stimulated sympathetic nerves to bridge the synaptic gap is noradrenaline.

This work, according to the Karolinska Institute, led to the Nobel Prize which he shared with Sir Bernard Katz and Julius Axelrod. Dr. von Euler's work has also stimulated the search for remedies against nervous and mental disturbances.

Dr. von Euler began his career at the Karolinska Institute in 1930 as assistant professor and advanced through the ranks to professor of physiology in 1939. He is a member of the Swedish Medical Research Council, and has served as chairman of the board of the Nobel Foundation since 1965. From 1965 to 1971 he was vice president of the International Union of Biological Sciences. He is a member of the Swedish Academy of Sciences.

He is the author of Noradrenaline (1956), Comparative Endocrinology with Hans Heller (1963), Structure and Function of Inhibitory Neuronal Mechanisms (1966); and many papers on endocrinology.

The Windsor Cutting Lectureship was established in 1973 by the faculty of the Department of Pharmacology, and supported by private contributions. It honors the memory of Dr. Windsor Cutting, professor and former chairman of the Department of Pharmacology, who also served as dean of the Stanford University School of Medicine (1953-57), and dean of the University of Hawaii Medical School (1963-71). Dr. Cutting died in 1972.

The lectures, given annually during the Winter quarter, feature speakers prominent in the field of pharmacology.

STANFORD--Dr. William Agras, professor of psychiatry, will speak on "Behavior Analysis and Modification" Wednesday (January 16) at the Stanford University School of Medicine.

The public lecture, the second in a series on recent advances in psychiatry, will be at 8 p.m. in Rooms M106 and M104 of the Medical School.

Agras was professor and chairman of psychiatry at the University of Mississippi Medical Center before he joined Stanford in 1973. He pioneered in research using behavior modification to deal with psychiatric problems.

The approach involves helping a patient change his environment or behavior to alleviate symptoms, instead of attempting to understand the causes of the problem through psychoanalysis.

A native of England, Dr. Agras, 44, graduated from the Middlesex Hospital Medical School in London, in 1955. Following a year of training in England, he became psychiatry resident in Canada, first in Montreal General Hospital and then at Montreal Children's Hospital.

The lectures are part of the Medical School's PROGRESS IN MEDICINE series offered to the community as part of a program of public education.

###

FOR FURTHER INFORMATION CONTACT: Hali Wickner 415: 321-5310

STANFORD--The Stanford University School of Medicine has received a $6,900 grant from the California Community Foundation of Los Angeles for support of students engaged in cancer research.

The contribution was made from the Foundation's Esther Sparks Cross Fund established by her will. It stipulated that a portion of the annual income from the Cross fund be given to Stanford University to provide scholarships for needy and promising medical students doing cancer research.

Eleven awards have been made to Stanford students since the Fund was established in 1970.

STANFORD--"Encounter Groups: A Current Perspective" will be discussed Wednesday (January 9) in a lecture at the Stanford University School of Medicine.

The lecture, open to the public, will be at 8 p.m. in Room M106 of the medical school. It will be delivered by Dr. Irvin Yalom, professor of psychiatry and co-author of a book on encounter groups.

A graduate of Boston University Medical School, Dr. Yalom is known for his work in group therapy and the relationship of hormones to behavior. At Stanford, he has launched a group counseling program for terminally ill patients, and a program to explore group therapy techniques in th treatment of alcoholics.

The lecture is part of the Medical School's Progress in Medicine series offered to the communi as a public service.

The first weekly series of five lectures on psychiatry includes a wide range of topics, from group therapy and behavior modification to obesity and sleep disorders.

STANFORD--A new series of five public lectures on recent advances in psychiatry will begin Wednesday (January 9) at the Stanford University School of Medicine.

The weekly presentations will include a wide range of topics, from group therapy and behavior modification to obesity and sleep disorders. The lectures are free of charge.

Dr. Irvin Yalom, professor of psychiatry, will present the first lecture on "Encounter Groups: A Current Perspective" at 8 p.m. in Room M106 of the Medical School Building.

He is co-author of the book "Encounter Groups: First Facts," the first scientific study of the encounter movement.

A graducte of Boston University Medical School, Dr. Yalom is known for his work in group therapy and the relationship of hormones to behavior. At Stanford in recent months he launched a group counceling program for dying patients and a program to explore group therapy techniques in the treatment of alcoholics.

The lectures are part of the Medical School's PROGRESS IN MEDICINE series initiated in 1965. According to Dean Clayton Rich, the lectures are offered to the community as a public service.

"Many exciting developments in medicine are being brought into being in medical centers throughout the world," said Dr. Rich. "Public understanding of these developments is important for intelligent participation in important social decisions."

He added some of the decisions have to do not only with community health and with the public investment in health care and research, but with the long range problems of world population, the management of artificial and transplanted organs, and the ethical and legal issues raised by the applications of the new knowledge of cell biology and heredity.

The lectures, featuring outstanding members of the Stanford medical faculty and distinguished visiting professors, will be given each Wednesday during the winter and spring quarter from 8 to 9 p.m. in the same location.

The other psychiatric lectures are:

JANUARY 16: "Behavior Analysis and Modification," by Dr. William Agras. Former professor and chairman of psychiatry at the University of Mississippi Medical Center, he is an authority on using behavior modification to deal with psychiatric problems. The approach involves helping a patient change his environment or behavior to alleviate symptoms, instead of attempting to understand the cause of his problem through psychoanalysis. Dr. Agras joined Stanford as professor of psychiatry in September 1973. He is a native of England and a 1955 graduate of the Middlesex Hospital Medical School in London.

-more-

JANUARY 23: "Relevance of Primate Research for Psychiatric Disorders," by Dr. David Hamburg, Reed-Hodgson professor in human biology. He is a leading authority in the study of hormonal responses to psychological stress, and past chairman of the Department of Psychiatry. Dr. Hamburg has been instrumental in developing the Laboratory of Stress and Conflict at Stanford, and also directs research on chimpanzees at Stanford's primate facility and in Africa. He is a 1947 graduate of the Indiana University School of Medicine, and received his professional training at Michael Reese Hospital in Chicago.

JANUARY 30: "Overweight and Obesity," by Dr. Albert J. Stunkard, professor and chairman of the Department of Psychiatry. He is a nationally known expert in the human eating disorders, including both obesity and pathological under-eating. A medical graduate of Columbia University, Dr. Stunkard is former head of the Department of Psychiatry at the University of Pennsylvania. He has identified and offered clinical descriptions of the "night eating syndrome," a pattern of food intake which characterizes patients who are resistant to weight reduction regimens. He also published the early observations of "dieting depression," a psychological response in some individuals attempting to lose weight. He is a recipient of the American Psychiatric Association's Hofheimer Prize for research.

FEBRUARY 6: "Sleep: What Can Go Wrong with It and What to Do When It Happens," by Dr. William C. Dement. A professor of psychiatry at Stanford, he is noted for his pioneering work in the field of physiology of sleep and dreams. He directs Stanford's Sleep Disorders Clinic where precise diagnostic and treatment methods for persons suffering from insomnia, hyperinsomnia narcolepsy and other sleep abnormalities are being developed. He and his colleagues have recently discovered a new syndrome related to insomnia. It is sleep apnea or cessation of breathing during sleep. Dr. Dement received his medical degree from the University of Washington in 1955 and obtained a Ph.D. in neurophysiology from the University of Chicago in 1957. He is a recipient of the American Psychiatric Association's Hofheimer Prize for his discoveries.

Following the psychiatric presentations, a series of lectures will be presented by the Department of Pediatrics. Details will be issued later.

STANFORD--Three Bay area universities will combine resources to train physicians in the skills needed to meet emerging problems in health care delivery.

Stanford University, University of California, San Francisco and University of California, Berkeley have been awarded $850,000 by the Robert Wood Johnson Foundation for an integrated three-year program to help strengthen ties between medicine and the community.

Beginning September, 1974 up to 12 physicians, called clinical scholars, will study and investigate nonbiological sciences related to medicine in a manner analogous to the graduate student. Once trained, clinical scholars may be teachers in new types of clinical and nonclinical education programs, organizers and administrators of community medical care systems and clinics, or health policy advisers to government and public service agencies.

The cooperative clinical scholar program is based on a similar program at Stanford University School of Medicine. Under a one year grant of $96,000 from the Johnson Foundation, Stanford is training six clinical scholars in a program headed by Dr. Halsted Holman, professor of medicine. According to Holman who will continue to head the Stanford program, joining with San Francisco and Berkeley will avoid duplication and broaden opportunities in the program.

Scholars will be affiliated with either Stanford or the University of California, San Francisco medical schools. However, they will be recruited and supervised by an interuniversity faculty committee and will draw on the facilities and personnel of all three institutions as needed.

"Inclusion of the Berkeley campus adds a new dimension to health care planning," notes Dr. Wallace Epstein, associate professor of medicine, who will head the program at San Francisco. "Scholars will be able to choose from a wide range of nonmedical courses and work with faculty members of all three campuses." The Berkeley program will be the responsibility of Sanford Elberg, dean of the graduate division.

In addition to continued clinical responsibilities, the scholars will pursue a curriculum that includes introductory courses in the administrative, economic, legal and social aspects of medicine, joint seminars, and independent research projects under the direction of faculty advisers from at least two of the campuses.

Current Stanford scholars are involved in such projects as assessing the quality of health care, developing medical information systems, planning health care for minority groups, evaluating medicine in urban areas and revising clinical education.

The combined clinical scholar program will be supervised by a governing board that includes citizens and physicians from the community as well as faculty and scholars. Such an integrated approach might contribute to the creation of a regional health care delivery system for the Bay Area, says Holman.

STANFORD--Stanford University Hospital has been sued by a patient for refusing to allow her to be given the controversial drug, Laetrile.

Mrs. Josephine Bergman, 49, and her husband, James, 766 Vista Grande, Los Altos, seek a court order to allow her to receive Laetrile at Stanford University Hospital where she is receiving chemotherapy for cancer by Stanford physicians.

John Schwartz, legal counsel for the Stanford Medical Center, said the hospital is prohibited by law to permit use of Laetrile on cancer patients.

According to Mrs. Bergman's complaint filed in Santa Clara Superior Court February 22, Dr. Stewart M. Jones, a Palo Alto general practitioner, had treated her with Laetrile at Stanford Hospital but was ordered to discontinue use of the drug.

In an affidavit filed with the court, Dr. Jones indicates he is not using Laetrile to treat the patient's cancer, but rather as "nutritional therapy."

Dr. Jones states, however, that although Mrs. Bergman "has reached the terminal stages of her disease, she has an excellent chance of significantly increasing her life span and a very fair prospect of surviving to an almost normal life span, provided she is permitted to resume her nutritional program immediately..."

This statement is contradicted by Laetrile's long and devious history. Claims of its value in cancer therapy have never been substantiated by scientists. Laetrile consists of a substance obtained from peach and apricot pits.

The federal Food and Drug Administration states flatly there is no acceptable evidence to justify use of Laetrile in clinical tests in humans. The California State Board of Health specifically prohibits its use on cancer patients. The drug is listed in the American Cancer Society's book of unproven cancer remedies, and the Canadian government has banned its distribution in that country.

The National Cancer Institute tested Laetrile several times as recently as 1973. The results of those tests were negative, according to Dr. C. Gordon Zubrod, director of NCI's division of cancer treatment, and Saul A.Schepartz, associate director for drug research and development.

In an article in California Medicine in June 1973, Dr. Frederick B. Hodges, director of the State Department of Public Health, wrote: "The action of Laetrile on living cancers has been studied *in vitro* and in man, and in none of these studies has it shown any demonstrable anti-cancer effect."

According to affidavits by Drs. Saul Rosenberg and Malcolm Bagshaw, noted Stanford cancer specialists, there is no basis that such substances known as Laetriles have a favorable effect in the treatment of human cancer either by reducing the tumor or prolonging the patient's life.

- more -

Schwartz said the Hospital believes the Laetrile used by Mrs. Bergman's physician was not labeled as to composition, toxicity, purity and other state and federal requirements. In addition, no authorization was given for its use as specified by the Hospital's Committee on Pharmacy and Therapeutics.

The attorney said Stanford Hospital must comply with standards promulgated by the Joint Commission on Accreditation of Hospitals. These are designed to maintain high quality care, and administration of a drug in this manner would be a violation of these standards.

George W. Kell, a Modesto attorney, filed the complaint for Mr. and Mrs. Bergman. Named in the suit are the Stanford University Hospital, Dr. Thomas A. Gonda, hospital director; Dr. Daniel Federman, professor and chairman of the Department of Medicine, and several John Does.

A hearing is scheduled Monday in San Jose.

STANFORD--The first hospital-based psoriasis day care center in the country opened last week at Stanford University Medical Center to provide inpatient care at outpatient convenience for those with psoriasis.

This innovative center, located at Stanford University Hospital's Hoover Pavilion on Quarry Road, enables patients to receive the treatment they need during the day and return to their families each evening. It is the beginning of an effort by Stanford dermatologists to make health care more available to the general population.

Director of the center is Dr. Eugene Farber, professor and chairman of the Department of Dermatology at the School of Medicine and a leading authority on psoriasis. Dr. William Watson, assistant professor of dermatology, is associate director.

Psoriasis, a common skin disorder that causes itching, scaling and redness, affects an estimated 6 million people in the United States alone. While no permanent cure is yet known, applications of appropriate salves provide effective control.

The majority of patients do not require hospitalization, but for the 5 to 10 percent who do, the average hospital stay is two or four weeks, says Farber. Another 10 percent with psoriasis on one quarter to one half of their bodies can benefit from a day care center where they can receive intensive therapy.

"Many psoriasis patients do not come into the hospital because they cannot afford to spend the time away from their families or jobs. Yet such patients may also find it difficult to care for themselves adequately at home," explains Farber.

He views the day care center as a practical compromise which makes it possible for more patients to obtain proper treatment without being hospitalized. For those who come to Stanford from other parts of the country, it means they can spend the night in a hotel or motel instead of a hospital. For children, it eliminates the fear associated with staying in a hospital.

A 2300-square foot area has been remodeled on the first floor of Hoover Pavilion for the day care center. The facility, adjacent to the dermatology inpatient unit, is expected to accommodate up to 20 patients a day by autumn, and 30 or 40 by next year. After an initial treatment period, patients can be followed periodically by their physician.

- more -

222---Psoriasis

Patients report to the center in the morning, five days a week for therapy sessions lasting seven or eight hours. Treatment, geared to the individual, involves special lights, baths and dressings, as well as local application of various preparations considered beneficial in reducing psoriatic lesions.

While under treatment, patients are free to use the center's facilities. These include two television lounges where occupational therapy is available and an audiovisual room with instructional media about psoriasis. At the end of the day, patients go home to their families until the next morning.

The hospital day care center offers several advantages, notes Dr. Paul Jacobs, associate professor of dermatology and head of the dermatology clinic. He expects it to reduce the cost of hospital treatment by as much as 50 percent. In addition to being closely followed throughout their therapy, patients have access to other hospital facilities if necessary. "It is important to care for the entire patient, not just the skin," Jacobs comments.

The audiovisual lounge contains a variety of helpful information on psoriasis. Films, slides and tapes are available to show patients what to expect in the course of the disease, and how to care for themselves at home and prevent further outbreaks.

Group sessions and informal discussions during the day are expected to help patients manage better when they go home. Although psoriasis is not contagious, many feel embarrassed or restricted by it, and the support of a group can help overcome this, Jacobs says.

Psoriasis day care is not a new idea. Farber pioneered day care centers for psoriasis in Europe with Dr. Charles Grupper of Paris several years ago.

Stanford's center is the first in the United States to be located in a hospital. Its organizers believe the concept holds tremendous potential for some other areas of medicine as well.

STANFORD--Howard Jack Wooling, assistant director of Stanford University Hospital since August of 1972, has been promoted to associate director.

The appointment, effective March 1, was announced today (February 21) by Paul Hofmann, deputy director of the Hospital.

With the promotion, Wooling's duties for certain patient care services will expand to include the Pharmacy and Medical Records Departments. Currently he has responsibility for three laboratories (cardiology, electroencephalography, and pulmonary function) as well as the Dietary, Physical and Occupational Therapy, and Respiratory Therapy Departments. Along with his line administrative functions, he is involved in several medical staff committees.

Wooling, 32, received his master's degree in public health from the University of California at Berkeley in 1972. He holds a bachelor's degree from Eastern Nazarene College (1965) in Massachusetts and a master's degree in education from Boston College (1967).

In addition to his full-time work at Stanford, Wooling serves as assistant minister for the Church of Christ in East Palo Alto.

STANFORD--Stanford University's research program on problems of stress and conflict has been awarded a $319,731 grant from the Commonwealth Fund of New York.

The three-year award was made to the School of Medicine to support the Department of Psychiatry's Laboratory of Stress and Conflict. It was announced today (Wednesday, February 20) by Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine, and Quigg Newton, president of the Commonwealth Fund.

In an interdisciplinary program that involves the medical, biological and social sciences, the laboratory has been studying hostility, aggression, and ways of coping with stressful experiences. Dr. David Hamburg, Reed-Hodgson professor of human biology, is director of the laboratory, which was organized in 1971 with the assistance of a previous grant from the Commonwealth Fund.

One of the laboratory's major interests is adolescence. "The prevalence of profoundly and pervasively hostile attitudes, the extraordinary spread of psychoactive drugs, and the upsurge of violence among adolescents sharply highlight the need for deeper understanding of this age group," says Hamburg.

He feels that aside from the first few years of life, adolescence--roughly the teenage years--is probably the most formative and critical time in life. How people cope with the stress of biological and social changes during this period can have lifelong implications, he notes.

In an effort to reach adolescents, the laboratory staff have developed an extensive peer counseling program in the local school districts. More than 450 students between 12 and 18 years old have been trained to counsel their fellow students with psychological, social or personal problems. In addition, nearly 100 adults in the schools have been trained as instructors and supervisors for the peer counselors.

-more

Peer counselors have also helped collect information on the patterns of drug use by adolescents so that more relevant drug education and prevention programs can be established. They work with youths in recreational and rehabilitational activities that provide rewarding alternatives to the use of drugs.

Patients who become hyperirritable and even violent under the influence of alcohol are being studied and treated at the laboratory's clinic on alcohol and violence. Related investigations are assessing psychological and social factors that make drug intake the preferred mode of dealing with life stresses.

Other areas of research include:

. Aggressive behavior of chimpanzees, particularly during adolescence. This work, in collaboration with Dr. Jane van Lawick-Goodall at the Gombe Stream National Park in Tanzania, will be enlarged when the Stanford outdoor primate facility is completed this spring.

. Sex hormones and aggressive behavior. Studies are underway to determine the relationship of sex hormones and behavior in infants, and also the association in normal men of male hormones and aggressiveness.

. Conflict and Psychotherapy. Through interviews with psychotherapists, an effort is being made to delineate effective methods of resolving hateful conflicts between individuals.

. Constructive alternatives to prison for adolescent offenders. Investigators are concerned with improving medical care and social opportunities for adolescent lawbreakers, particularly when offenses involve alcohol, drugs or psychiatric problems.

The human capacities for hostility and aggression are so complex that the resources of many disciplines are needed to help understand them, says Hamburg. Comprehensive scientific examination of these problems, he adds, may lead to improved ways of resolving human conflicts.

STANFORD--Dr. Mary Ellen Avery of McGill University, a noted authority on lung diseases of the newborn, will deliver a talk at Stanford University School of Medicine Friday, February 22, as the first Katharine McCormick Distinguished Lecturer.

She will discuss "Recent Studies in the Pulmonary Surfactant" at 4:00 p.m. in Room M106. The lecture is open to physicians and health professionals of the community.

Professor and head of pediatrics at McGill University Faculty of Medicine for the past five years, Dr. Avery is also physician-in-chief at Montreal Children's Hospital. In June, she will become the first woman to head a major department at Harvard Medical School as the Thomas Morgan Rotch Professor of Pediatrics and physician-in-chief at Children's Hospital Medical Center in Boston.

Dr. Avery is well-known for her work on the role of the lung surface material (surfactant) in hyaline membrane disease, a respiratory disorder of premature infants. She has helped demonstrate that a deficiency of surfactant, which normally prevents lung collapse, is an important factor in the pathology of hyaline membrane disease.

A native of Camden, New Jersey, Dr. Avery received her A.B. in 1948 from Wheaton College in Massachusetts, and her M.D. in 1952 from Johns Hopkins University. She wrote The Lung and Its Disorders in the Newborn Infant, and coauthored another book Diseases of the Newborn.

The Katharine McCormick Distinguished Lectureship was established recently to bring outstanding women physicians and scientists to the School of Medicine. It honors the late Katharine D. McCormick who left a $5 million bequest to Stanford in 1969 to aid programs in the School of Medicine, particularly those "for the encouragement and assistance of women in ...medicine."

Last year, the Professional Women of Stanford Medical School sponsored an unofficial McCormick Lecture when they invited Dr. Estelle Ramey of Georgetown University to speak at Stanford. At their suggestion, the lectureship was formally established for 1974.

STANFORD--An experimental satellite communication system has dramatically improved the delivery of health care in 14 remote Alaskan villages and should be expanded to other isolated areas in the state, Stanford University researchers have reported.

The satellite service enables native health aides--who have at most only 16 weeks of training, yet provide all the primary medical care in their communities--to obtain needed daily consultation from doctors at an Alaskan field hospital.

With telephones virtually non-existent in these bush regions of central Alaska, the health aides previously were forced to depend upon unreliable high frequency radio contact to reach the doctors. Because of interference from storms, mountain ranges and atmospheric disturbances, such radio contact is possible only 14 per cent of the time.

To provide more dependable communication and make expert consultation available to the health aides and their patients, the National Library of Medicine's Lister-Hill Center for Biomedical Communications funded an experimental satellite service that began in August of 1971.

Satellite communication is more reliable than radio, since the signal is transmitted from one point up to the satellite and back down to another point, bypassing most interference.

The project has utilized NASA satellite ATS-1 (Applied Technology Satellite-1), parked 22,300 miles above the equator, and small ground stations located in each village. The system is operated and maintained by the Indian Health Service and the University of Alaska Geophysical Institute at Fairbanks

The Lister-Hill Center contracted with researchers at Stanford to evaluate the project and propose recommendations for the development of a permanent system.

Two members of the Stanford research team-Edwin Parker and Heather Hudson from the University's Institute for Communication Research--reported their findings in a recent issue of the New England Journal of Medicine, a scientific journal.

They found that the installation of satellite radio in the native villages improved the frequency of contact with Tanana Hospital (a 26-bed field hospital staffed by three doctors) by over 500 per cent. Perhaps more significantly, the number of medical cases discussed with a doctor increased nearly 400 per cent.

"Both health aides and doctors are convinced that the quality of health care has improved," the authors said.

The increased contact with doctors, they said, had the triple effect of increasing the health aides' medical knowledge, boosting their confidence in their work, and making patients more apt to follow their instructions.

- more -

222---Satellite

Because of the impact the experiment has had, the Stanford researchers propose that a permanent satellite system be implemented which would be expanded "to serve other remote and isolated areas in Alaska."

Much of the state's native Indian and Eskimo population is scattered in about 175 villages with populations between 25 and 500, they pointed out. The villages are typically without electricity and draw their water from rivers. Reliable communication, as in the experimental villages prior to the advent of satellite radio, is non-existent.

In an interview, Parker described the Stanford recommendations: "We're proposing that low-cost ground stations be installed in the 175 remote Alaskan communities where the need for this service exists," he said. "Manufacturers have indicated that the stations would cost under $15,000."

Such a system, Parker said, could utilize RCA circuits on the Canadian national satellite, Anik II.

The NASA ATS-1 could not be used for the permanent system, he said, since it is an experimental satellite without the capacity for the desired 24 hour a day operation. It was launched in 1966 with a life expectancy of two years.

Parker noted that the Indian Health Service is presently studying various methods to fund a permanent system.

Aside from the major benefit of improving health care in the isolated villages, he said, the satellite has other medically-related uses. The current experimental system has enabled patients at Tanana Hospital to talk to their families in the villages for the first time.

It has also been used to transmit a lecture from the University of Washington Medical School to a premedical class in genetics at the University of Alaska. Additionally, a doctor on St. Paul Island in the Bering Sea regularly uses the satellite to consult with specialists in Anchorage.

The Stanford research team, in addition to Parker and Hudson, includes Dr. William Fowkes, assistant professor of medicine, and Bruce Lusignan, associate professor of electrical engineering.

###

Editors: You are invited to send your representatives to a demonstration of the proposed permanent satellite communications system on Saturday, February 23, at 12 noon, at Point Reyes, California. A small ground station, similar in design to those proposed for use in the Alaskan villages, has been installed at Point Reyes. Using this station and the Canadian satellite, Anik II, a two-way "satellite" conversation will be held. Additionally, Senator Ted Stevens of Alaska will discuss prospects for development of the permanent system. For directions on how to reach the demonstration site, please contact Professor Parker at (415) 321-1200, ext. 2755.

SCIENCE WRITERS: Following is a statement by Dr. Avram Goldstein on the significance of isolation and partial purification of the first chemical opiate receptor, a story mailed for AM papers Friday, February 15, 1974. There are also some helpful answers and questions gleaned during an interview with Dr. Goldstein by the Stanford Medical Center News Bureau.

STATEMENT BY DR. AVRAM GOLDSTEIN

In our research laboratory we are trying to understand in biological terms what narcotic addiction is all about. The major scientific question about addiction can be divided into two parts: first, how can heroin produce its remarkably powerful gratifying effect that makes people use it over and over again? Second, what kinds of biochemical changes occur in the brain when an addict becomes hooked on heroin that make it so difficult to get off and to be cured?

How the heroin acts on the brain is a question that could be asked about any drug—how does it work? And the first step in understanding how narcotic drugs work is to isolate and purify the receptors in brain cells that these chemicals combine with. To explain, drugs work by interacting with specific molecules in brain cells or cell membranes. This combination triggers a chemical event that leads to what we call drug action. These special molecules are the receptors to which narcotic drugs fit, like keys fitting into their proper locks.

In our work during the past few years we studied mouse brain fragments and learned how to isolate and partially purify a receptor molecule that combines with a narcotic drug closely related to morphine. This receptor is a proteolipid, a protein molecule with fatty or lipid properties. We have estimated its molecular weight and found that the receptor combines specifically with narcotics and also with narcotic antagonists—drugs that block the "high" narcotic addicts seek. The receptor is found almost exclusively in nervous system tissue (the brain, spinal cord) and the nerve net of the intestine that controls intestinal contractions.

We think the receptor isolated thus far is probably involved in the pain-killing effects of narcotics because it is present principally in that part of the brain in which pain relief is known to occur. This is in the lower part of the brain stem called rhombencephalon.

The receptor has not been completely purified yet, but the report in *Science* describes the partial success along that road, which we expect to lead to an increased understanding of brain chemistry and eventually addiction.

(more) 2/13/74

QUESTIONS AND ANSWERS

Q. What is the next step in your research?

A. There is evidence we are dealing with a family of receptors mediating different actions of narcotic drugs. We think one receptor in one part of the brain mediates the rewarding-euphoria effect that causes addicts to use narcotics. Another receptor in a different part of the brain mediates the pain-killing action. We are now in the process of isolating and purifying different receptors in mouse brain tissue to see how they differ chemically.

Q. Your findings so far are limited to the discovery of a receptor in mouse brain. Do similar receptors exist in human brain?

A. Very similar molecules are almost certainly involved in human narcotic addiction. Dr. Eric Simon's group at New York University, and Dr. Solomon H. Snyder's group at Johns Hopkins University have shown the presence of opiate receptors in membranes from human brains obtained at autopsy, although they did not attempt to extract and purify these receptors. Many of the effects of heroin and morphine are almost identical in mice, rats, and other mammals including man. Mice and rats can become addicted to narcotics and suffer withdrawal symptoms when deprived of the drugs afterwards.

Q. Why was it difficult until now to extract a narcotic receptor from the membranes of brain cells?

A. The reason is technical. Most drugs that act on the brain dissolve easily in cell membranes. The drugs have to be soluble because the brain is a difficult place to get into. But this very fact makes it difficult to isolate receptors because once a drug enters the cell membranes it interacts not only with receptors but also with other nonspecific molecules. In 1971 we published a paper describing the technical problems that would be encountered in any attempt to isolate opiate receptors, and we argued that only opiates of a certain kind have access to the receptor sites. Accordingly, we sought to discover such binding sites in mouse brain.

Q. Can you describe the steps in which this was done?

A. To find the receptor we used a radioactive form of an opiate related to morphine which has all the effects of morphine. The drug is available in two forms which contain the same atoms but have a different spatial layout. In their chemical configuration, these two forms of the drug are mirror images of each other, like left and right hands.

The right-hand form binds to the narcotic receptor, but the other form of the opiate does not. The difference between the amount of attachment of the two forms of the drug represents the amount of actual chemical combination with the receptor molecule.

The receptor is separated from other membrane material by a series of chemical steps. Because the receptor is a proteolipid, which does not dissolve in water, various solvents such as chloroform, methyl alcohol, and heptane had to be used to extract it. Then the receptor was purified by removing contaminating substances by treatment with ether and also by the process of column chromatography with solvent mixtures. The receptor has not been completely purified yet. It represents about 1/1000 of the protein in a mouse's brain.

Q. What do you mean, the receptor has been purified partially?

A. The goal is to obtain the receptor proteolipid in absolutely pure form, so that its exact composition, structure, and shape can be determined. We want to know especially how combining with an opiate molecule like morphine changes the structure and function of the receptor. To accomplish these aims we have to remove every trace of impurity from the receptor. This we have not yet done.

Q. What do you believe is the significance of this work?

A. Eventually, it could have enormous importance in dealing with narcotic addiction. This is an area of great public concern where social policy is being made on the basis of extremely little scientific understanding of the problem. We tend to think of heroin addiction now as a disease but we don't know what kind of disease.

There is some evidence that heroin addicts may have some really abnormal function in their brains. It is even possible that through repeated use of narcotics the drug receptors in brain cells are changed in some irreversible fashion either in their structure and function or through the biochemical system of which they are part. If we understood these changes in receptors—assuming that they occur—we might have the basis for a new approach to the treatment of addiction. This approach might involve finding chemical means for restoring these abnormal receptors to their normal configuration and function.

Better understanding of how the chemistry of the brain changes when a person becomes addicted might make it possible to restore healthy cell function more rapidly.

With better knowledge of the function of opiate receptors we might make progress in another area. If we could show, for example, any differences between receptors that mediate pain-killing action and those mediating gratifying-euphoric effects, we could develop new nonaddictive opium-like pain-killing drugs.

This has been a goal of pharmacologists for the past 100 years. We do not yet know whether it can be done. But certainly this would be the possible outcome of a clear differentiation of these two types of opiate receptors.

STANFORD--Sleep, what can go wrong with it and what you can do when that happens, will be the subject discussed by Dr. William C. Dement, professor of psychiatry at Stanford University Medical School, at the PROGRESS IN MEDICINE lecture on Wednesday (February 6).

The fifth in the series of free public lectures will be held at 8 p.m. in Memorial Auditorium on the Stanford campus.

Dr. Dement is noted for his pioneering work in the field of physiology of sleep and dreams. He directs Stanford's Sleep Disorders Clinic, where precise diagnostic and treatment methods for persons suffering from insomnia and other sleep abnormalities are being developed.

Dr. Dement and his colleagues have recently discovered a new syndrome related to insomnia. It is sleep apnea or cessation of breathing during sleep.

Dr. Dement received his medical degree from the University of Washington in 1955 and obtained a Ph.D. in neurophysiology from the University of Chicago in 1957. He is recipient of the American Psychiatric Association's Hofheimer Prize for his discoveries.

This is the last in the series of psychiatric presentations. The series will continue with lectures presented by the Division of Cardiology, beginning in March. Details will be issued later.

STANFORD--Stanford University Medical School will be developing, and concurrently evaluating, a system for monitoring the quality of medical care at Stanford Hospital.

The six-months study is being supported by a $39,900 contract from the California Regional Medical Program. It is in addition to other quality of care studies underway at the Medical Center.

The study comes at a time when the California Medical Association and the California Hospital Association are proposing that hospitals implement a quality assurance program. This is in response to recent federal legislation requiring new systems to monitor medical care.

The quality assurance program attempts to monitor patient care in the hospital, identify problems in both professional and administrative areas. It will set up systems for determining if a patient should be hospitalized and for how long, proper services to be rendered, and alternative treatments.

According to Dr. Edward Rubenstein, associate dean for postgraduate education at Stanford, the need for quality assurance programs is widely recognized, but actual operation of such systems has proceeded slowly. There is resistance to universal adoption of a standard system for determining diagnoses, admission procedures, courses of care, for example. "Quality" has not been adequately defined, and the cost benefit of such an assurance program is unknown, says Rubenstein.

The planning of a quality assurance program, and concurrent evaluation of it, is being undertaken by the office of postgraduate medical education at Stanford. Working with Rubenstein are Drs. Raymond J. LaSure, James F. Fries, William H. Forrest, Jr., and Harold C. Sox, Jr.

Rubenstein says that Stanford is "now developing a comprehensive system but we plan to proceed slowly and to identify areas for evaluation as we go."

The investigators have identified common disease-problem categories leading to hospital admission, and subcommittees will develop criteria related to these diseases and/or problems. Monitor systems to detect possible deficiencies in care will be developed, as well as an administrative framework to correct problem areas.

The aim is to develop flexible criteria of care which take into account the various problems of the patient. The doctors will use the clinical data computer system now in operation at Stanford to assess the relation between process of care and the eventual outcome, to evaluate results, and to provide feedback to physicians

A further aim is to foster implementation of this system within the 12 community hospitals in northern California which have formed a consortium with Stanford for postgraduate medical education.

Rubenstein reports that a subcommittee is also engaged in designing evaluation of the program itself.

STANFORD--The increasing roles of computer and engineering technology in the study of heart disease will be discussed by Dr. Edwin Alderman, assistant professor of cardiology, in a free public lecture at Stanford University Wednesday (March 27).

The lecture, entitled "New Methods to Diagnose Heart Disease," will begin at 8 p.m. in Memorial Auditorium. It is the third in a series of four presentations by Stanford Medical School on recent advances in cardiology.

Co-director of Stanford's cardiac catheterization laboratory, Alderman is an expert on computer methods of diagnosing heart function.

He and his colleagues utilize computers to analyze 10-hour tape recordings of patients' heart action, as well as data obtained from cardiac catheterization (in which long narrow tubes are threaded through blood vessels into the heart to measure heart functions).

Stanford engineers are now developing an instrument that will harmlessly take pictures of organs inside the human body, using sound instead of light or X-rays. This device is expected to be very valuable in medical diagnosis, particularly in cardiology.

Alderman is consultant for the Stanford-NASA biomedical technology team. A medical graduate of Johns Hopkins University, he received his professional training at Bronx Municipal Hospital and Montefiore Hospital in New York.

The cardiology lectures are part of the Medical School's Progress in Medicine series, initiated in 1965.

STANFORD--Two scientists at Stanford University School of Medicine have been named Macy Faculty Scholars for 1974-75.

Dr. Eric Shooter, professor of genetics and biochemistry, and Dr. Irving Weissman, assistant professor of pathology, have each been awarded a scholorship from the Josiah Macy, Jr. Foundation of New York to support research during their sabbatical year.

The award was announced recently by Dr. Clayton Rich, vice president for medical affairs and dean of the Medical School, and Dr. John Powers president of the Macy Foundation.

Dr. Shooter, a molecular neurobiologist, will spend his sabbatical at the University of Geneva. He will do research in the pathology department there with Dr. Bernard Fulpius on the characterization and isolation of receptors important in the development of the nervous system.

A member of the Stanford faculty since 1963, Dr. Shooter received a Ph.D. degree in 1950 from the University of Cambridge in England. He was awarded a doctor of science degree from the University of London in 1964 for distinguished work in biochemistry.

Dr. Weissman will divide his sabbatical time between the Salk Institute in La Jolla and the Sir William Dunn School of Pathology at Oxford University in England. An immunologist interested in how the body's defenses can help fight cancer, he will investigate the thymus gland, studying leukemia induced virus tumors with Dr. Melvin Cohn at La Jolla and lymphocyte differentiation with Dr. J. L. Gowans at Oxford.

He graduated from Stanford Medical School in 1965 and was a postdoctoral fellow and a research associate in the Department of Radiology before joining the faculty in 1969.

STANFORD--Bruce Marsh, a well-known Canadian radio and television broadcaster who was awaiting a heart transplant at Stanford University Hospital, died suddenly last night (March 18).

Marsh, 48, a native of Toronto, was found dead in a Los Angeles hotel room. Death was caused by an apparent heart attack.

The popular announcer, a nationally-known figure in Canada, was in Los Angeles to visit friends and handle a short broadcasting assignment. When he failed to show up for a dinner engagement, friends went to his hotel room, and found him dead.

The victim of four heart attacks during the past 10 years, Marsh had been waiting in Palo Alto since mid-November for a heart transplant.

During the past three weeks, he appeared on numerous San Francisco news and television shows to discuss the recent shortage of organ donors which has slowed the heart transplant program at Stanford, as well as the kidney transplant program at the University of California, San Francisco.

Since Marsh's first television appearance, two heart transplants have been performed at Stanford--one on March 2 and another today (March 19). Prior to that time, Stanford had not received a heart donation since December.

Marsh is survived by his wife, Elizabeth, and two teen-aged sons. Funeral arrangements will be handled by the A.W. Miles Funeral Home of Toronto.

The community is invited to visit Stanford University Hospital's new psoriasis day care center at an open house this Friday and Saturday, March 22 and 23.

Members of the staff will be available to show visitors around the center Friday from 9 a.m. to 5 p.m., and Saturday from 9 a.m. to 12 noon. Refreshments will be served.

The center, believed to be the first hospital based day care center for psoriasis in the country, opened last month. It is located at the Hospital's Hoover Pavilion on Quarry Road.

Patients with psoriasis can obtain the treatment they need during the day at the center and return home to their families each evening

Psoriasis is a common skin disorder that produces reddened, scaly spots or patches on many parts of the body. It affects some 6 million people in the U.S. The majority do not require hospitalization, but an estimated 10% can benefit from intensive day care.

Dr. Eugene Farber, professor and chairman of the Department of Dermatology at the School of Medicine, is director of the center. Dr. William Watson is associate director. –30– cr

Vicki Hays, Stanford's ace swimmer from Fullerton, set a meet record in the 50-yard breaststroke during the women's national intercollegiate meet March 14-17 at Penn State University.

Hays, referred to as "the one girl team" by her teammates, also placed second in the 100-yard individual medley, second in the 100 yard breaststroke, and set six new Stanford records in other events.

First place went to Arizona State, which swept an invitational meet at Stanford a few weeks earlier. The University of Miami, University of Washington, University of New Mexico, and UCLA took the next four places.

The Stanford team placed 11th in point totals out of 91 participating university entries in the meet, sponsored by the American Intercollegiate Athletics for Women (AIAW).

Coach Betsy Weeks clocked Hays at 0:30.90 as she splashed to first place.

Hays set new Stanford records in both the 50-yard and 100-yard breaststroke (1:07.58) and 100-yard individual medley (1:01 12), 200 yard medley relay (1:55.12), the 400-yard medley relay (4:12.20), and the 400-yard freestyle (3:50.77).

Mei Ong of Malaysia placed 5th in the 200-yard medley, and Kathy Heinze of Saratoga, 12th in the 100 yard butterfly.

Hays, Ong, Sue Trupin of Champaign, Ill , and Heinze placed 8th in the 400-yard medley relay and 5th in the 200 yard medley relay, with Nan Leuschel of Portland, Ore., swimming in place of Heinze.

STANFORD--Two major administrative appointments at Stanford University Medical Center were announced today (March 18) by Dr. Clayton Rich, vice-president for medical affairs.

Dr. Thomas A. Gonda, director of Stanford Hospital, has been appointed medical director of the Medical Center and associate dean for clinical affairs of the School of Medicine.

Paul B. Hofmann, deputy director of the Hospital, has been appointed director of the Stanford Hospital and Clinics.

The changes, part of an administrative reorganization in the Medical Center, will consolidate the management of all patient-care functions, Dr. Rich said. The Center's financial operations were merged last September.

"The revised organization largely is a response to the increasing interdependence of the Medical School, Hospital and Clinics," he said. "The aim is to achieve a high degree of coordination and effectiveness to meet the changing needs of the entire Medical Center."

In his new position, Gonda will supervise the patient care activities of the medical staff within the Hospital and Clinics. He will work closely with community and faculty physicians, as well as residents, interns and postdoctoral fellows.

He will also coordinate the development of the Medical Center's quality assurance and professional standards review programs.

Hofmann will assume responsibility for the administration of the Hospital and Clinics.

The appointments are effective April 1.

Gonda, 52, has had a distinguished career as a psychiatrist, teacher, researcher, and administrator.

He has been director of Stanford Hospital since 1968. Twice he served as acting chairman of the Medical School's Department of Psychiatry, from 1955-56 and again from 1958-61. He has been an associate dean of the Medical School since 1967.

-more-

222--Appointments of Gonda and Hofmann

A native of Vienna, Austria, Gonda obtained both his A.B. (1942) and M.D. (1945) degrees from Stanford. He received further professional training at San Francisco Hospital and the Langley Porter Clinic.

He served as clinical director of psychiatry at San Francisco Hospital from 1949-51, and was chief of neurology and psychiatry at the Veterans Administration Hospital in San Francisco the following two years.

After a year in private practice, Gonda joined the faculty at Stanford in 1954 and was promoted to professor of psychiatry in 1965. The author of numerous book chapters and scientific articles on human behavior, he served as a visiting professor at Oxford University in 1961-62.

Hofmann, 32, becomes one of the youngest University Hospital directors in the country and the youngest in Stanford's history. He has served as the Hospital's deputy director since June of 1972.

He is also a lecturer in the Medical School's Department of Family, Community and Preventive Medicine, and teaches a popular course in Stanford's Health Services Administration program.

Before coming to Stanford, Hofmann was associate administrator at San Antonio Community Hospital in Upland, California, and a lecturer in hospital administration at the UCLA School of Public Health.

A native of Portland, Oregon, he received his B.S. (1963) and Master of Public Health (1965) degrees from the University of California, Berkeley.

After two years as a research associate in hospital administration at the Massachusetts General Hospital's Laboratory of Computer Science, he became assistant director of the Laboratory and also instructor in computer applications at the Harvard School of Public Health.

He has published numerous articles in professional hospital journals on a variety of topics, including the use of computer technology in hospitals. He is a member of the American College of Hospital Administrators, the American Hospital Association's counsel on research and development, and the California Hospital Association's committee on hospital licensure.

Hofmann, his wife Lois, and their 18-month old daughter, Julie, live on the Stanford campus.

STANFORD--Dudley C. Kenworthy, associate general secretary at Stanford, has been named director of development for the Stanford University Medical Center.

His appointment, effective April 1, was announced Monday (March 18) by Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine, following a nationwide search.

In his new position, Kenworthy will head the Medical Center's fundraising efforts. During the past five years, the Center has received an average of $9 million a year from private gift sources.

Currently, Kenworthy directs the University's major gifts program in Northern California, Hawaii, and the Pacific Northwest. Both his present position, and his new one in the Medical Center, are related to the current $300 million Campaign for Stanford, begun two years ago.

Kenworthy succeeds Marshall Virello who died last November.

A native of Glendale, Kenworthy attended Pasadena schools, and received his AB from Stanford in 1951 and his MBA in 1953.

Before joining Stanford in 1959, Kenworthy held positions in personnel and industrial relations with several corporations. At Stanford he has been responsible for programs of annual giving, major gifts, building projects and long-range studies.

He has been active in several community and civic organizations including the Palo Alto YMCA, the Sierra Club, and the Sempervirens Fund.

His wife, Marion, is a member of the Stanford class of 1952, and holds a Stanford AB and AM in Education. She is counsellor at Saratoga High School. They have three children.

The Kenworthys live in Menlo Park.

STANFORD--"Exercise in the Prevention and Treatment of Heart Disease," will be discussed by Dr. Robert F. DeBusk, assistant professor of cardiology, in a public lecture at Stanford University Wednesday (March 20).

The lecture, second in a series of four presented by Stanford Medical School on recent advances in cardiology, will begin at 8 p.m. in Memorial Auditorium. It is free of charge.

DeBusk is director of Stanford's cardiac rehabilitation program, designed for heart attack victims and patients recovering from open heart surgery. The program consists of exercise testing and training, physical therapy, and psychological and dietary counseling.

In the future, DeBusk hopes to extend the program to individuals with early symptoms of heart disease, including stable chest pain or angina pectoris.

"Many people can be put on an exercise program to help determine whether it can prolong life not only for heart attack victims, but for others in the early stages of heart disease as well," he says.

A 1964 graduate of Stanford Medical School, DeBusk received his professional training at Stanford and Harvard.

The cardiology lectures are part of the Medical School's Progress in Medicine series, initiated in 1965.

STANFORD--Dr. I. Robert Lehman, professor of biochemistry, has been named chairman of the Department of Biochemistry at Stanford University School of Medicine.

The appointment, effective September 1, was announced today (Wednesday, March 13) by Medical School Dean Clayton Rich.

He succeeds Dr. Paul Berg, head of the department since 1970, who is relinquishing his administrative responsibilities to return to teaching and research.

Dr. Lehman's research on the mechanism of DNA synthesis and degradation has contributed to scientists' understanding of the cell's genetic apparatus. His most recent work has involved the joining of DNA molecules by the enzyme DNA ligase, an enzyme known to be required for replication and recombination (exchange of hereditary material).

An alumnus of Johns Hopkins University, Dr. Lehman received his A.B. in 1948 and his Ph.D. in biochemistry in 1954. From 1954 to 55 he was a fellow at the McCollum-Pratt Institute of Johns Hopkins. He then joined the Department of Microbiology at Washington University School of Medicine in St. Louis, first as an American Cancer Society fellow, then as an instructor.

In 1959, Dr. Lehman was appointed assistant professor of biochemistry at Stanford. Two years later he was promoted to associate professor, and in 1966 he became a professor.

The 49-year-old biochemist is author of numerous scientific publications, and an associate editor of the Journal of Biological Chemistry. He is a fellow of the American Academy of Arts and Sciences and a member of the Johns Hopkins Society of Scholars. He has also received the Henry J. Kaiser Award for excellence in teaching at Stanford Medical School.

STANFORD--New evidence that a body chemical may trigger crises in patients with sickle cell anemia was reported Tuesday (March 12) by a team of Stanford University researchers.

Sickle cell anemia is a hereditary blood disease which almost exclusively affects black people. In a crisis, which can last several days or weeks, the victim suffers extreme pain and is frequently disabled.

The Stanford investigators first reported 18 months ago that sickle cell crises may be initiated or enhanced by one of the prostaglandins, fatty acids manufactured in many tissues of the body.

The new findings indicate that the same prostaglandin type produces two related effects on the red blood cells of sickle cell anemia patients: an impairment in the ability of the cells to carry oxygen, which results in decreased oxygen supply to body tissues; and an increased intake of calcium, which can cause the cells to become more rigid and sickle more easily.

The researchers--Dr. Paul L. Wolf, associate professor of pathology and head of the clinical laboratories at Stanford, and Dr. Israel Rabinowitz, Stephen Berman, and Neal Shikuma--reported their findings at the annual meeting of the American Association of Pathologists and Bacteriologists in San Francisco.

"These findings support the suggestion that prostaglandin is a contributing factor in the sickling process," Wolf said.

Red blood cells of sickle cell anemia victims become rigid and elongated, shaped like crescents or sickles. Unlike normal blood cells, which are round and flexible, they have difficulty moving through the body's smaller blood vessels.

The result is seriously impeded blood flow and reduced oxygen supply to various body tissues, causing severe pain, increased infection, and often malfunction of body organs and disability.

Approximately 50,000 American blacks have sickle cell anemia. Another 2 1/2 million carry the gene for the disorder and have sickle cell trait, though they usually do not suffer symptoms of the disease.

Prostaglandins are capable of acting in various ways on body tissues in very minute quantities. They have been used in clinical trials in the United States, Sweden and elsewhere to induce labor and abortion, and to treat asthmatics.

In their experiments, the Stanford investigators added prostaglandin type E_2 to blood samples from individuals with normal blood and patients with sickle sell anemia and sickle cell trait.

They found that the presence of the chemical produced a 33 per cent decrease in the oxygen carriage of blood cells of sickle cell anemia patients. There was a slight increase in the normals and patients with sickle cell trait.

In a companion study, they determined that prostaglandin E_2 caused a marked increase in the intake of calcium into blood cells of sickle cell anemia victims.

Wolf suggested that the possible role of prostaglandin E_2 in the sickling process is to affect or damage the cell's membrane so that more calcium enters. This, in turn, increases cell rigidity and accelerates sickling of the cell.

With these new findings, scientists may now attempt to find drugs that can aid in the treatment of sickle cell anemia patients by inhibiting the production of prostaglandin E_2.

STANFORD--"Your Diet and Your Heart" will be discussed Wednesday (March 13) by Dr. John S. Schroeder, assistant professor of cardiology, in a lecture at Stanford University.

The public lecture, first in a series on recent advances in the prevention and treatment of heart disease, will be delivered at 8 p.m. in Stanford's Memorial Auditorium. It is free of charge.

Under Schroeder's direction, Stanford Hospital a year ago began serving patients a model, low-fat menu in an educational program on the role of diet in heart disease prevention.

Questionnaries returned by over 100 patients three months after their discharge from the Hospital, indicated that at least half had modified their home diets in some way to cut down on fat intake.

A graduate of the University of Michigan Medical School, Schroeder is noted for his studies of contributing factors in heart attacks and evaluation of high risk cardiac patients. He is also chief cardiologist on Stanford's heart transplant team.

The cardiology lectures are part of the Medical School's Progress in Medicine series, initiated in 1965 as a public service to the community.

SAN JOSE--A court order, sought by a Los Altos woman to allow her to take the illegal drug Laetrile while a cancer patient at Stanford University Hospital, was denied Wednesday (March 6) by Superior Court Judge John S. McInerney.

"The court is being asked to order a hospital to do something which the hospital does not feel it has the legal right to do...and feels is medically unwise," Judge McInerney wrote in a five-page opinion.

In a complaint filed last week, Mrs. Josephine Bergman, 49, had sought the order to permit her to receive doses of the medicine which is prepared from peach and apricot pits.

Mrs. Bergman said Dr. Stewart M. Jones, a Palo Alto physician, has been treating her with Laetrile at Stanford hospital, but discontinued its use on orders from hospital officials.

"The hospital has the right to require of Dr. Jones that he obey reasonable rules and regulations," the judge wrote. "One such rule relates to the use in the hospital of only those drugs... whose pharmaceutical integrity can be reasonably assured.

"The Laetrile previously used by Mrs. Bergman is alleged not to meet this requirement and no evidence to the contrary has been introduced."

At a hearing Monday, Stanford's staff counsel Merel Glaubiger contended that use of Laetrile is illegal and allowing it now would leave the center open to prosecution and a flood of requests from other cancer patients.

George W. Kell, attorney for the Bergmans argued the issue essentially was one of freedom of choice, involving the patient's "right to choose what to do with her body."

The court said the patient had freely chosen to seek care in the Stanford hospital, and as such she subjects herself to reasonable hospital rules and regulations.

The U.S. Food and Drug Administration says there is no acceptable evidence to justify use of Laetrile on human beings, and the California Cancer Act prohibits its use specifically on cancer patients.

Proponents of Laetrile have argued that use of the drug as a vitamin is legal. But Stanford attorneys said there is no exception in the law for the administration of Laetrile as nutritional therapy.

Mrs. Bergman was quoted Thursday in the Stanford Daily as saying "I'm not giving up. Now I have to wait until I'm discharged, but I don't feel bad that I lost. The story is out in the open and I think that's good."

According to the campus newspaper, both she and Kell indicated they will press on with their legal battle, this time for a permanent injunction against the hospital.

The hospital has approximately three weeks to respond to the plaintiff's charges before the court schedules a hearing on the permanent injunction. ### Mailed, March 7, 1974

STANFORD--The Sleep Disorders Clinic at Stanford University School of Medicine has been awarded a $60,000 gift from Pfizer Laboratories, New York.

Dr. William C. Dement, professor of psychiatry and director of the clinic, notes that the financial support will enable the clinic to continue to study patients, a basis for further understanding of sleep.

"Exploratory research in sleep disorders has far to go," says Dr. Dement, "particularly in patient care, and we need all the assistance possible to keep our clinic running."

A check for $20,000 will be given to the clinic annually for three years. In making the initial presentation of the check to Dr. Dement this week, John Abeles, associate medical director of the pharmaceutical firm, explained the company's motivation:

"Sleep disorders is a new field, and information accruing from pure scientific exploration is important and useful to us as drug manufacturers as well as to medicine. We need to learn directions to take in this still murky area..."

Physicians, says Dr. Dement, have made little progress in sleep problems, as millions become dependent upon drugs for help, and reports of drug misuse grow. Disorders are variously described as neurologic, untreatable, imaginary, psychiatric or psychosomatic.

More research, he feels is needed in the study of what sleep itself is. Dr. Dement and his associates have been developing systematic approaches to diagnosis of sleep disturbances.

FOR IMMEDIATE RELEASE
STANFORD –

A new series of four public lectures on recent advances in the prevention and treatment of heart disease will begin Wednesday, March 13, at Stanford.

The weekly lectures, presented by members of the Medical School's Division of Cardiology, will focus on a wide range of topics, including the importance of diet and exercise, new diagnostic methods, and prevention of sudden death. The lectures are free of charge.

The first talk, "Your Diet and Your Heart," will be delivered by Dr. John S. Schroeder, assistant professor of cardiology, at 8 p.m. in Memorial Auditorium. The 45-minute lecture will be followed by a question and answer period.

Under Schroeder's direction, Stanford Hospital a year ago began serving patients a model, low-fat menu as part of an educational program on the role of diet in heart disease prevention.

"The crucial diet problem of most Americans is not malnutrition, but overnutrition," Schroeder says. "Many experts now believe that to prevent the epidemic of heart disease in this country, Americans must change their dietary habits throughout their lifetime, preferably beginning in childhood."

A graduate of the University of Michigan Medical School, Schroeder is noted for his studies of contributing factors in heart attacks and evaluation of high risk cardiac patients. He is also chief cardiologist on Stanford's heart transplant team.

The cardiology lectures are part of the Medical School's Progress in Medicine series, initiated in 1965. They are offered to the community as a public service, according to Dean Clayton Rich.

The other lectures in the cardiology series, all scheduled Wednesdays at 8 p.m. in Memorial Auditorium, are as follows:

March 20: "Exercise in the Prevention and Treatment of Heart Disease," by Dr. Robert F. DeBusk, assistant professor of cardiology. DeBusk is director of Stanford's cardiac rehabilitation program, designed for heart attack victims and patients recovering from open heart surgery. Begun last December, the program consists of exercise testing and training, physical therapy, and psychological and dietary counseling. DeBusk graduated from Stanford Medical School in 1964 and received his professional training at Stanford and Harvard.

March 27: "New Methods to Diagnose Heart Disease," by Dr. Edwin L. Alderman, assistant professor of cardiology. Co-director of Stanford's cardiac catheterization laboratory, Alderman is an expert on computer methods of diagnosing heart function. He and his colleagues utilize computers to analyze 10-hour tape recordings of patients' heart action and data obtained from cardiac catheterization (in which long narrow tubes are threaded through blood vessels into the heart to measure cardiac functions). A medical graduate of Johns Hopkins University, Alderman is consultant for the Stanford-NASA biomedical technology team.

April 3: "Sudden Death: The Problem and How to Prevent It," by Dr. Donald C. Harrison. Harrison is William G. Irwin professor and chief of cardiology at Stanford. He is nationally known for his studies of various drugs used in the treatment of life-threatening abnormal heart rhythms. In recent years he has pioneered in the application of computer and engineering technology to cardiology. He is developing numerous monitoring and warning devices for high risk patients to prevent sudden death. Under his direction Stanford has established a Center for the Study of Sudden Death. A graduate of the Medical College of Alabama, Harrison received his professional training at Harvard and Stanford. He has been chief of cardiology at Stanford since 1967.

STANFORD--In a unique application of the Red Cross Blood coverage plan, a group of employees at Stanford University Medical Center have volunteered to donate blood to insure blood coverage for all Spanish surname patients at Stanford University Hospital.

The Alianza Latina (Latin Alliance), which represents the Spanish-speaking employees of the Medical Center, has arranged with the American Red Cross-Stanford University Blood Center to have group coverage extend to all Spanish surname patients in the hospital, except those with hemophilia or leukemia.

This plan is effective immediately. The first six volunteers gave blood at the Stanford Blood Center today (Friday, March 1).

Under the standard group coverage plan, if 20 percent of the group members donate a pint of blood during the year, the entire group as well as dependents are entitled to receive unlimited blood for that year without being charged for replacing it. There is a processing fee, but that is usually covered by insurance companies, according to Harold Horoho, director of the Red Cross-Stanford Center.

"The Alianza has taken the standard plan a step further to apply to patients," explains Tony Rodriquez, manager of training and development and coordinator of the project. "While we don't expect many people will use the plan at first, the important thing is that such a service is now available to a group of people who might not otherwise be able to afford it."

This plan is just one way the Alianza, which has about 150 members, is trying to meet the needs of Spanish speaking patients, points out Delores Silva, chairperson of the group.

Horoho says he doesn't know any other Red Cross units that provide such coverage. He feels that the concept deserves a one year trial and that it could be a model for certain other groups.

"It's a gamble for the Blood Center because we're dealing with an unknown quantity; there's no way of predicting how many patients will be in the Hospital," he notes. "However, the concept is a means of reaching a segment of the community which may not ordinarily give blood."

He explains that the Red Cross hopes to stimulate donations throughout the county in the name of Alianza Latina. Volunteers will also receive the standard coverage for themselves and their families.

STANFORD – Most critically ill newborn infants who would otherwise have died, today recover without handicaps because of various supportive measures now available.

This is the story from the Stanford University Hospital's intensive care nursery and Premature Infants Research Center, now entering its eleventh year of operation.

Julie, for example, was born prematurely and weighed just four pounds. Her blood condition required that she have a transfusion minutes after birth.

Shortly afterwards she developed respiratory problems severe enough to require a lengthy period on a respirator to assist her breathing. More transfusions were required. Doctors put her chances to survive at only 40%.

Julie was born at Stanford University Hospital in 1967 and today she is a bright, healthy, highly intelligent six-year-old.

Infants like Julie born today have a much greater chance of survival than she had. Today, the overall survival rate for infants with respiratory distress syndrome is 85%, according to Stanford nursery statistics.

Survival for all infants admitted to the Stanford intensive care nurseries (ICN) in the first half of 1973 was 92%.

Follow-up studies of survivors who had mechanical ventilation (oxygen assistance) between 1962 and 1969 at Stanford show that more than 80% have no handicaps, neurologically or intellectually. Incidence of handicaps decreased in the latter part of the period studied.

Dr. John Johnson, assistant director of the Stanford nurseries, points out that 95% of those studied probably would not have survived at all without treatment.

Dr. Philip Sunshine, director of nurseries, and Dr. Johnson list several developments in the care of critically ill infants at Stanford that have helped bring about this improvement.

They cite more extensive monitoring, new equipment, more diagnostic tools, and changes in therapy and general procedures.

About 700 infants are admitted to the ICN yearly. An additional 50 are admitted to the Premature Research Center annually, where the intensive care is supported by a grant from the General Clinical Research Centers Branch of the National Institutes of Health.

Respiratory distress is the most common complication of premature infants, and doctors at Stanford have developed methods of therapy to improve the survival of these infants.

Today respiratory distress syndrome (RDS) occurs in approximately one to 2% of all live births, affecting 20 to 25% of all prematurely born infants in the U.S.

According to Dr. Sunshine, mechanical ventilation techniques have been most important in Stanford's success in altering the picture of RDS mortality.

RDS, or hyaline membrane disease, are terms often used interchangeably to describe the developmental phenomenon.

(more) 4/30/74 cr

Treatment aid, says Dr. Sunshine, is to support the infant until he produces a surface active material to line the airway and keep the alveoli, the tiny air sacs in his lungs, from collapsing.

Normally this material is manufactured during the late fetal period before birth, but may be absent in premature infants.

"We treat HMD as one would treat a heart attack. We treat the complications it brings and give the infant time to heal himself," says Dr. Sunshine.

Recently research has begun to indicate that steroids administered to the mother a day or two before birth may cause the enzyme material to be made more readily by the infant.

The use of oxygen in the care of the premature infant is a subject of great controversy, since prolonged use of high concentrations of oxygen can be damaging to both the lungs and eyes of the baby.

Stanford doctors have developed specific criteria for initiating oxygen therapy. Their aim is to have a shortened exposure to oxygen, starting at lower concentrations.

Anticipating the need for this therapy is an important development in the Stanford ICN during the past 10 years. According to Dr. Sunshine, "the ideal management of an infant with RDS is to anticipate the infant at risk to develop the syndrome and to monitor that infant carefully. Time is of utmost importance. . . ."

Doctors also require regular temperature checks. The premature infant has very poor temperature control. The smaller he is, the greater his chance of survival if his temperature and that inside his incubator are maintained at specific levels. At these levels his oxygen consumption is minimal.

Not only premature infants require intensive care. Recently Stanford ICN has placed increasing emphasis on identification of small-for-dates infants: those full-term babies weighing under 2500 grams (5.5 lbs). Only infants delivered before 37 weeks are termed premature. More than 20% of the infants admitted to the Stanford nurseries are small-for-dates.

The problems and complications of such infants are markedly different from those encountered in an infant of the same weight, but who suffers from early growth retardation. The small-for-dates infant normally doesn't have respiratory distress syndrome, but hypoglycemia (low blood sugar) and pneumonias are characteristic problems.

For example, it is standard prodedure at Stanford to monitor glucose frequently in such babies to prevent hypoglycemia before symptoms may overtly appear. As a result, says Dr. Sunshine, there are fewer complications of the disorder.

Another factor in lowering newborn mortality has been improved infant transport systems. The Stanford heliport is a well-known feature, with more than 200 infants flown or transported by ambulance annually to the ICN from outlying community hospitals.

Improvements in infant transport systems have lowered mortality in transit to about 15% from the 25 to 35% rate of 10 years ago, says Dr. Sunshine.

Among new procedures in the PRC and ICN are earlier feedings, more extensive use of mother's breast milk, and feeding by IV. There is a "walking blood donor program," where Medical Center staff may periodically donate the very small amounts of blood needed for a baby.

Parents now have a more extensive role in the nurseries. Many parents come as often as three times a day to learn to feed and care for their baby who has an extended stay in the intensive care nurseries.

For the future, doctors expect even further reductions in infant mortality. But the real breakthrough would be prevention of prematurity. At Stanford, work in that respect is centered on family counseling, nutrition, and prenatal care.

Says Dr. Johnson, "Doctors can anticipate and correct a lot of complications, but prevention is the ultimate goal."

1. Electronic monitors keep a constant watch as this three-and-a-half pound baby girl sleeps in Stanford University Hospital's Premature Infant Research Center.

2. A premature baby who began life weighing just a pound-and-a-half receives care from her mother in the Stanford Premature Infant Research Center.

3. Dr. Philip Sunshine, director of Stanford's intensive care nurseries, checks a baby whose breathing is assisted by a respirator. Stanford Medical School student Eddie So (right) and Joann Tsuchimochi, RN, look on.

STANFORD--June commencement will mark what may be the last chapter in the 77-year history of the Stanford University School of Nursing.

The nursing school will close this summer as 18 young women of the last class receive their baccalaureate degrees.

The future of nursing education at Stanford remains uncertain.

A study committee in 1973 had recommended phasing out the present program leading to a baccalaureate degree, and replacing it with a two-year master's program.

That new program can only be implemented by a combination of private and federal support. Unfortunately, federal funding for nursing education has dwindled in recent years and "realistically, we must have some outside financial involvement for our plan to go ahead," says Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine.

The study committee had reasoned that the present program was too small, and had little effect on the overall health care delivery system, but the impact of graduating 30 nurses with advanced training and prepared for expanded roles would be substantial.

In the current program, students complete two years of undergraduate university work before entering the nursing school for three years of study leading to a baccalaureate degree in nursing. New students have not been admitted to that program since 1972, pending development of a new curriculum.

Dr. Rich expresses disappointment at the "undesirable and unwanted demise" of the nursing program.

And so do nursing students, alumnae and faculty who hope that a strong graduate nursing program may someday become a reality.

Several members of the last class are completing or working toward additional degrees. Some will receive their degree in subjects like English or psychology as well as nursing; one student will receive a master's degree in education; another plans to continue study at law school, perhaps combining careers in medical law.

In the last class 52 percent of the students received their two (and frequently more) years of undergraduate work at Stanford.

Most of the nursing school faculty was terminated in 1972 and 1973. Of the current faculty, two are retiring and the remaining two are seeking other positions.

-more-

222--School of Nursing

Grace Ringressy, director of the school for the past 28 years, will retire this summer. She received her diploma from the school in 1932, then was awarded undergraduate and graduate degrees in nursing and nursing administration from the University of California at Berkeley.

She notes that the changes in education of nurses in recent years left Stanford as the only private, non-sectarian university on the West Coast to offer the bachelor's degree in nursing.

Currently, baccalaureate programs are offered at the UC campuses in San Francisco and Los Angeles, at several campuses of the California state university system and at three private schools.

Former hospital or diploma programs are rapidly closing as the trend for more college-educated nurses grows. Increased numbers of community colleges are offering AA (two-year associate of arts degree) nursing programs.

The school had its beginning in 1897, when six nurses were graduated from the Lane Hospital Training School in San Francisco.

The baccalaureate program was offered by 1917, and two years of undergraduate preparation has been required for students since 1939.

The school moved to Palo Alto with the medical school in 1959. Although the complete faculty of 14 came to the campus, the change was a major one in the philosophy of nursing education at Stanford.

On campus, it was possible for students to utilize the resources of the total university community. They did not depend on hospital service as student nurses of early hospital training programs.

Principles, in addition to practice skills, became an important part of the professional nurse's education.

Although the future of nursing education at Stanford is uncertain, alumnae of the school are actively pressing for a new program.

The Stanford Nurses Club, with a large membership, "is not giving up," according to its president, Marlene Handy.

"Our members are very sad," she says. "The older San Francisco group is very close, and has strong feelings about the school. There is a sadness, but also a real determination to see a new program established."

(ADVANCE) FOR RELEASE TUESDAY, APRIL 30, 1974

Editors: Release date for this story has been set to coincide with Dr. Hayflick's talk at the University of Southern California Andrus Gerontology Center.

STANFORD--The "fountain of youth" lies not in hoaxes and crazes, a Stanford medical microbiologist says, but rather in practical scientific research in aging, particularly the research on cells.

Dr. Leonard Hayflick, speaking at the University of Southern California Andrus Gerontology Center Tuesday (April 30), said that gerontology specialists can make progress toward solving the questions of aging.

"The notion that the biology of aging is too vastly complex to yield to experimentation is, I believe, a myth," he said.

Dr. Hayflick was awarded the Biomedical Science and Aging Award today from the USC Gerontology Center. He is well-known for his discovery that normal fetal cells have a predetermined capacity to divide, about 50 times in man, and that adult human cells divide fewer times according to the age of the donor. Then they stop dividing and die.

The microbiologist believes that cells gradually acquire errors in their genetic information, and the "program" is simply played out, resulting in aging and an ultimate limit to the span of life.

Presenting the Isadore and Esther Kesten Memorial Lecture in Los Angeles, Dr. Hayflick suggested that the capacity for cell divisions is rarely completed in man, that functional losses occur in the cells before they stop dividing This produces age changes long before normal cells reach their maximum limit of division.

This phenomenon of the finite lifetime of normal cells, he says, "cannot be attributed to any trivial cause, but is best explained by intracellular events undoubtedly genetically based."

The goal of research in aging, he maintains, is not simply to increase longevity.

"If longevity is to be increased merely by extending the years of our infirmities, then the goal is not worth seeking," he said.

"The goal that appears to be not only more desirable but indeed more attainable is not the extension of longevity, but the extension of our most vigorous and productive years."

-more-

Researchers have noted that the life span appears to be fixed at about 90 years in man, regardless of the state of technological or medical progress. Modern medical achievements have resulted in more people reaching that fixed life span.

Life expectancy at birth has increased in recent years, but at age 65 to 70 it has remained essentially constant.

Dr. Hayflick says that even if cancer, heart disease, stroke and other major diseases were conquered, the human life span would be basically unaffected.

The human life span, he says, will not be significiantly changed until the underlying, non-disease related, biological causes of aging are either slowed or stopped.

Claims of super-longevity, he said, should be taken with skepticism. Adequate scientific proof has not been given to substantiate the claims for longevity. Current claims, he says, "should be regarded as unproven if not outright hoaxes."

Dr. Hayflick noted that biological gerontology has long been regarded as a pseudo-science, lacking scientific respectability.

He cited hoaxes like the yogurt craze of the early 1900's and said that few researchers are willing to risk their reputations in a field with such a stigma.

He called for more scientific interest in the field, and increased support for research.

STANFORD--Research in molecular genetics will have major consequences for curing the sick and for developing novel plants of particular advantage to agriculture rather than creating supermen, says a Stanford University biochemist.

"I can imagine attempts to create particularly advantageous domestic animals and plants," says Dr. David Hogness, "but I do not find that schemes to create supermen by such techniques are credible."

Many laymen, including Congressmen, have often expressed concern about future possibilities of "perfecting the race" by altering genes.

But Dr. Hogness, writing about the human use of genetics in a new book The Great Adventure, says no one would want to perform such potentially horrendous experiment.

With the exception of efforts to cure hereditary defects and finding answers to diseases such as cancer, the practical advantages of man's search for new gene combinations will be restricted to agriculture, according to Dr. Hogness.

Among the possibilities would be to create plants that would not need nitrogen fertilizers, the biochemistry professor said. "This might be done by inserting bacterial genes that allow the needed nitrogen to be obtained from the air, rather than from fertilizers in the soil."

In agriculture, knowledge of heredity has allowed construction of new plant varieties "because the aims are better defined, the system is simpler...and ethical objections are tenuous," Dr. Hogness said.

But man has only just begun to tap the reservoir of genes made available by centuries of mutation and natural selection.

"The yield from different crops has been augmented by selecting for resistance to particular pests or for growth cycles to fit different growing seasons," he said.

"Short, stiff-strawed rice varieties developed at the Rice Institute in the Philippines increased the yield from 1,200 to more than 9,000 pounds per acre.

"This extraordinary increase soon allowed the Philippines to become an exporter of rice, and we may expect that the food supply will be profoundly altered as these strains are introduced throughout Asia.

-- more --

"Seedless watermelons are now available to those with inhibitions about spitting, and pineapples have been developed that will fit a number two can."

Dr. Hogness said there is some urgency in preparing a proper base by moving genetics to the center of man's educational experience.

"The knowledge we have acquired regarding the molecular structure of genetic information forms the unifying link and fundamental basis for all terrestrial life," he said.

"It indicates that man's potential for changing life through the use of his intellect is far greater than we would have guessed even 30 years ago.

"It is much as if we had taken a drink from Alice's elixir, and had shrunk smaller and smaller, until we could see the individual atoms of which genes are composed."

Dr. Hogness said pessimists who fear the advance of man's knowledge in molecular genetics are unduly concerned.

"In any case, it is not possible to halt that advance, so interrelated are all aspects of biology," he said.

"The millions we spend on a 'cure for cancer' will inevitably reveal some of the basic mechanisms for the integration of viral DNA into human chromosomes..."

(DNA or deoxyribonucleic acid is the substance of heredity. Its purpose is to perpetuate a species by cell division and provide the information for constructing the proteins that develop and operate the cell).

Viral DNA can now be used as a vehicle to insert genes from one species into the cells of another, Dr. Hogness said.

This can be done by first attaching DNA containing the genes from one species to the viral DNA in a series of reactions carried in the test tube. The resulting hybrid DNA is then inserted into cells of the other species.

In experiments at Stanford, animal genes have been inserted into bacteria, Dr. Hogness added, but we may reasonably suppose that in the future it will be possible to insert bacterial genes into plants or animals, or mix genes from any two species.

"The implications of this type of genetic mixing are indeed radical," Dr. Hogness said. "We can imagine the insertion of new genes into the cells of genetic cripples to provide the functions that cannot be contributed by the defective genes."

He said it is recognized that many diseases are hereditary. There are about 2,000 of these ranging from anemias to diabetes and mongolism. As more of these are treated and prevented, they will occupy an increasing fraction of the physician's load.

STANFORD -- He's a very good man," says the elderly woman sitting in the doctor's waiting room. "Please don't take him away from us."

The "good man" in this case is Sergio Noriega, one of the first in a new class of health professionals--the physician's assistant.

Noriega is a 29-year old Mexican who for four years was a medical corpsman in the Navy. He now sees 25 to 30 patients a day in the predominantly Spanish--speaking agricultural community of Gonzalez, where he assists three family doctors.

A similar story has developed in Boulder Creek, a small California village nestled in the mountains between San Jose and Santa Cruz. There physician's assistant Ron Tachibana, another former Navy corpsman, aids two general practitioners. Tachibana, too, has established his own clientele in the area, and counsels many patients on their emotional problems.

Noriega and Tachibana, along with 14 others, were members of the first class of physician's assistants (PA's) trained at the Stanford Medical Center. They graduated last June, after completing a two-year training program. Thirteen graduates from that class now have jobs as PA's in California and another is working in Michigan.

Nationally, there are over 60 paramedic training programs supported by the federal government or approved by the American Medical Association. These programs, though similar in purpose, are by no means identical. They vary in length--four months to four years--and in name--physician's assistant, primary care associate, MEDEX (Medical Extension), and nurse practioner.

Most are designed to aid over-worked family doctors in the delivery of primary health care, particularly in underserved rural or ghetto areas. Others provide specialized training in emergency medicine, surgery, or child care.

Stanford's is one of two primary care PA programs established in California since the state enabling law was passed in 1970. The other, cosponsored by UCLA and the Charles R. Drew Postgraduate Medical School in Watts, has also graduated one class.

Several nurse practitioner programs also have been launched in the state, including those based at the University of California's San Francisco, Los Angeles, and Davis campuses. These provide specialized medical training on top of nursing school education.

To date, 1600 trainees have graduated from the various nationwide PA programs; some 900 are involved in delivering primary care to families in underserved areas.

On the job, primary care PA's perform a myriad of tasks under the supervision of their doctor-employers.

They take medical histories, perform physical examinations and diagnostic workups, counsel in preventive medicine (including diet, social habits and family planning), and participate in the management of chronic diseases.

They also give injections, suture minor wounds, apply and remove casts, handle emergency calls, and perform office laboratory work.

With this assistance, the physicians are freed to focus their skills where they are needed most. Perhaps more significantly, they are able to treat more patients.

"By having Sergio here, we're able to offer and provide care to a lot of people who otherwise might not get it," says Dr. James Fassett, who supervises Noriega in Gonzalez.

(more) 4/24/74

Fassett, a 1945 graduate of Stanford Medical School, was raised in Gonzalez and has practiced there for 25 years. Tremendously popular and well-respected in the community, he has had patients drive out to his home and knock on his door at 2 a.m. complaining of a headache.

With an extremely busy, entirely rural practice, Fassett believes his office is the ideal setting for a PA.

Noriega echoes those sentiments: "That's really what the PA program is all about," he says, leaning forward in his chair for emphasis. "The over-worked rural family doctor may finally get some relief because of us. The influx of PA's also may entice other doctors to the country.

"To me," he continues, "the most frustrating thing is the fact that there are so many people who needed treatment and so much uncaring by the medical profession. The doctors are all concentrated in Palo Alto and San Francisco. There's no one out here treating the farmers and migrant workers, the low and lower middle class people."

For the lower income patient, he adds, a language barrier often poses another obstacle to adequate medical care.

Spanish-speaking people comprise 75 percent of the patient population treated by Noriega and the three doctors he works with in Gonzalez—Fassett, Leonard Nevarez, and June Dunbar.

Because of this, the doctors say, Noriega is even more valuable than he might be otherwise.

"Even though we all speak Spanish, it's just not the same as with Sergio," Fassett says. "The patients feel he'll understand their problems better—their background, their traditions, their family ties.

"In this area, he's been a tremendous asset. He's particularly good with children, just a natural. Mexican patients are very concerned with children. It's the center of their life, so this is very important to them."

Noriega, himself the father of two girls and a boy, was named Sergio after a character in a Russian novel his mother was reading when he was born. He has a unique feeling for the Mexican patients, and believes he is providing better care in a Spanish-speaking community than he would be elsewhere.

"When a Mexican woman comes in and tells me she's tried to treat herself by drinking tea or putting a patch of mustard plaster on her stomach, I don't laugh at her," he says. "I know what she's talking about.

"To get these patients to tell you what's bothering them, you often have to go at it in a roundabout way," he adds. "Certain things in their culture are taboo and you have to be careful not to insult them."

Just as Noriega's language and cultural ties with the community have made him so valuable in Gonzalez, Tachibana's counseling talents have filled a need in Boulder Creek. Each day he commutes 30 miles through the mountains from Sunnyvale, where he lives with his wife and five-year old daughter, Lisa.

"Ron's an exceptional individual," says Dr. Kenneth B. Reed, his employer, who has practiced in Boulder Creek for 12 years. "He now sees many patients about their emotional problems as well as physical. I can't; I just don't have the time. That's an added bonus I didn't anticipate when I hired him."

Tachibana feels he's more able to attend to patient's emotional needs because he's not a physician.

"Patients are less reluctant to ask me questions about their illness or therapy since I'm not an M.D.," he says. "Many times they don't want to ask the doctors because they think their questions are dumb."

Tachibana saves the last appointment of each day for patients who have problems they want to talk about.

"That way we can take as long as we want without worrying about a waiting room full of other patients," he says. "In these situations you really have to listen to the patients—not only what they're saying, but also what they're not saying. A lot of illnesses are related to home problems. If you can do something about the home problem, you can often do something about the illness."

In large part because of their special interests and capabilities, Noriega and Tachibana have been extremely well-accepted in their communities. For several months both Fassett and Reed solicited opinions and criticisms from their patients. The result: no adverse comments and many compliments.

(more)

But the issue of patient acceptance is tied in with another, potentially more troublesome one—the threat of malpractice suits. This fear, heightened by the rising number of large malpractice awards in recent years, has led many physicians who could use PA's to shy away from hiring them.

A PA's personal malpractice insurance is attached as a rider to the doctor's policy, as is an office nurse's. Under this arrangement, the PA is liable for his own acts, but liability extends to the doctor-employer, who ultimately bears the responsibility for all services provided in his practice.

Those involved in current programs feel that physician's assistants will help reduce, rather than increase, the number of malpractice suits, because their presence on the health team will improve the quality of care.

"I had a lot of misgivings about patient acceptance and the medical-legal aspects of having a PA at first," Reed says. "But as time goes by, I worry about both a lot less. It's very evident that Ron adds to the quality of care rather than detracts from it."

Dr. Michael Dennis, director of Stanford's PA program, is another who shares this belief.

"Most malpractice suits occur against doctors forced to see 80, 90, or 100 people a day," Dennis says. "It's hard to see that many people every day without either being too abrupt or missing something.

"Probably 40 of those 100 people simply need to talk with someone about a minor problem. The PA can handle them and allow the doctor to devote his time to the more serious problems. With the PA helping in this manner, the doctor is less likely to miss something."

The early returns would seem to substantiate this viewpoint. To date, only two malpractice suits have been filed nationwide against PA's and their employers. Both cases were dismissed before reaching the courtroom.

In minimizing the risk of malpractice and maximizing the PA's effectiveness, there appear to be three major concerns: the PA must not try to assume too much responsibility; the physician-employer must exert the proper supervision; and informed consent must be obtained from the patients.

"Something you really have to look for in a PA," Fassett says, "is his recognition of his own limitations. Sergio knows his capabilities very well. He doesn't do anything he feels incapable or unsure of.

"Typically, he'll find something abnormal, come to me and tell me about it, and I'll ask him, 'What do you think we should do?' Then we'll confer and decide on the appropriate treatment."

The issue of determining what constitutes appropriate supervision is one that lawmakers, PA's and physicians have been grappling with since the first experimental PA program was started at Duke University in 1965.

"Does supervision mean that the doctor has to be looking over your shoulder or down the hall, or does it mean he occasionally can go out to lunch and leave you in charge?" Noriega asks. "I personally feel it's a question that has to be answered individualy by each doctor and his PA."

California law simply says that the physician must review the findings of the PA following an evaluation and consult with him before therapeutic measures are initiated. Stanford's Dennis was one of those involved in writing the 1970 state law.

"We agonized over the wording for a long time," Dennis says. "Some wanted to specifically call for immediate supervision. Others wanted to say 'supervision by electronic means.'

"The problem is that the PA's effectiveness in terms of man-hours declines in proportion to the amount of immediate supervision provided by the physician. The ultimate aim is to strike a balance between maximum effectiveness and responsible supervision."

Dennis feels that the key to achieving this delicate balance is mutual trust between the parties involved.

"In any adviser-advisee relationship," he says, "the amount of immediate supervision depends on trust. In this case, the trust develops in a triad among the PA, the physician, and the patient.

(more)

"The patient must recognize who the PA is—not another M.D., but an individual whom the doctor has confidence in and delegates a great degree of responsibility to."

Under California regulations, written consent must be obtained from patients before care can be rendered by a PA, except in life-threatening situations. Consent need not be given for each visit, but on an annual basis. Additionally, the PA is required to identify himself to each patient.

"You don't walk in and say, 'I'm sorry I'm a PA,' because the patient will freak out," says Don Massie, another Stanford graduate now working in Corning, Calif. "You have to be very professional about the whole thing."

Despite the routine identifications, many patients find it easier to simply address the PA as "doctor."

"You can explain 'til you're blue in the face that you're not an M.D., but they'll still call you 'doctor,' " Tachibana laughs. "It's practical, I guess, since there's really no title that goes along with the role."

Compared to a doctor's training—which begins in undergraduate years with premed courses, carries through four years of medical school, then internship and residency—the PA's education seems pretty elementary. But the graduates of Stanford's first class, which includes nine former military medics and six registered nurses, feel they were well-prepared for their on-the-job responsibilities.

Cosponsored by Foothill Junior College in Los Altos Hills, the two-year program consists of classroom instruction, rotation through clinical services at Stanford or an affiliated institution, and practice with a community physician.

"The tools I use every day come from the training program," Noriega says. "At the end of the two years you have a tremendous amount of medical knowledge. On the job, you refine that knowledge daily."

Tachibana regards his previous experience as a corpsman and his training at Stanford as the foundation which he builds upon.

"I feel cheated if I don't learn something new each day," he says.

Aside from an ongoing education, the knowledge that they're doing something very worthwhile, and the satisfaction from helping people, the job has its other rewards.

Nationally, the average salary is a little above $15,000, Dennis says. Some PA's, given little responsibility by over-cautious doctors, are paid receptionist's wages. Others, operating on a lucrative fee for service basis, earn over $20,000 per year.

"Your salary depends," Noriega says, "on what the doctor thinks you're worth to his practice, whether it's bringing in more patients, giving him more time off to be with his family, or freeing him to attend continuing education seminars."

Though many PA's enjoy being called "doctor," few have plans to attend medical school and obtain an M.D. degree.

"Before I started my job I had visions of going on to med school," Tachibana says. "But if things continue as they have, I don't see any need for it. I'm quite satisfied as a PA."

Noriega never thought seriously about medical school, but after his stint as a Navy corpsman he, too, sought a career in medicine. He worked as an orderly and licensed vocational nurse before entering the PA program.

"I wanted to put the things I had learned into practice, without having to go to school for 14 years," he says. "We have a lot less money to pay back than the M.D.'s."

With that, Sergio Noriega smiles and pauses for moment. He shakes his head as he thinks about the $10-$15,000 in loans many medical students must repay after they enter practice.

It is inevitable, some would argue, that many young doctors become eager to cash in on their long, expensive, and demanding medical education. Because of this, they are drawn away from primary care into the more lucrative specialties, away from the country to the more affluent suburbs. And because of this, they help create the need for primary care PA's.

"There's really no need for me to go back to school," Noriega says. "Here I have all the responsibility I want, all the patient acceptance I want, and most important, all the satisfaction I want."

STANFORD--Dr. Leonard Hayflick, professor of medical microbiology at Stanford University School of Medicine, will receive the Biomedical Science and Aging Award and the Isador and Esther Kesten Memorial Lectureship from the University of Southern California Gerontology Center.

The awards, which will be presented at a banquet April 30 in Los Angeles, honor achievement and distinguished contributions in the field of aging. Dr. Hayflick will also present a lecture on the USC campus Tuesday morning (April 30) titled "New Wrinkles on Aging."

Dr. Hayflick receives the awards for his work on the biology of aging. In growing normal human and animal cells outside the body, he found that the older the donor, the fewer times the cells divided. The number of cell divisions also depended on the average life span of the species.

Dr. Hayflick believes that cells gradually acquire errors in their genetic information, and the "program" is simply played out, resulting in aging and an ultimate limit to the span of life.

The microbiologist also played a key role in persuading the government to permit use of human cells for production of safer and cheaper vaccines.

More than 50 percent of polio vaccines used in this country are produced in the strain of human cells developed by Dr. Hayflick. Many other vaccines produced in these cells will soon be available here as they are now in many other countries.

Dr. Hayflick has spoken out on a variety of issues, including the need for standardizing vaccine production, cancer research, and cell banks.

As a recipient of the Kesten Lectureship, he will stay at USC's Andrus Gerontology Center for several days to lecture and exchange ideas with faculty and students. He will also present a paper before a Sigma Xi, national honorary scientific society, meeting.

Dr. Hayflick established the cancer-virus research program at Stanford in 1968. He also established a central human cell bank which supplies normal human cells to research labs throughout the world.

He received his Ph.D. from the University of Pennsylvania.

He is active in numerous scientific organizations, and has received honors from the National Cancer Institute, the Commission for Aging Research, and the U.S. Gerontological Society, among others. He has often served as a consultant to government, industry and international scientific committees.

STANFORD--A team of investigators at Stanford University School of Medicine has discovered a new mechanism controlling cell division and cell maturation in human tissue.

The finding makes it possible to do detailed studies of cancer cells and determine why they are perpetually growing in comparison to normal cells which have a limited life cycle and die.

The team, led by Dr. John H. Frenster, clinical associate professor of medicine, reported its new findings in the March 22 issue of Nature, a scientific journal.

All cancer cells have at least two things in common. They grow in an abnormal uncontrolled fashion, and this ability to grow "out of control" is passed on from one generation of cancer cells to the next. When an abnormal malignant cell grows and divides it produces another malignant cell that "pays no attention" to the regulatory mechanisms that govern a normal cell.

"Human cancer cells display unusual types of cell division and fail to mature and die at normal rates," explained Dr. Frenster.

"This maturation defect preserves the cancer cells in a state of perpetual youth, and accounts for the accumulation of increasing numbers of cancer cells in cancer patients."

Dr. Frenster and his group analyzed human bone marrow cells taken directly from patients. They utilized techniques newly developed by Dr. Frenster in which molecular probes are inserted into living cells and are visualized by high-resolution electron microscopy.

The Stanford scientists studied the activity of deoxyribonucleic acid (DNA), the hereditary material packed in the nucleus of the cell. DNA is the substance of the chromosomes and the chemical language in which the construction manual for living things is written. The purpose of DNA is to perpetuate a species by cell division and to provide the information for constructing the proteins that develop and operate the cell.

DNA is copied into RNA which is the source of information for protein synthesis.

Dr. Frenster and his associates have found that during normal cell division and maturation there was a progressive decrease in RNA and DNA synthesis, suggesting that the copying activities of these molecules are strongly repressed and inactivated.

Scientists have long suspected that some cancers may be a disease of DNA, but the scientific evidence has been spotty and circumstantial.

"The finding is important because it now allows an analysis of cancer cells to determine if the repression mechanism is malfunctioning in such cells," Dr. Frenster said.

The Stanford team included Shirley L. Nakatsu, Marilyn A. Masek, and Sharon Landrum, research assistants in Dr. Frenster's laboratory. The study was funded by a grant from the National Cancer Institute and the American Cancer Society, and by a research scholar award from the Leukemia Society.

STANFORD--Dr. Norman E. Shumway, noted heart transplant pioneer, has been appointed professor and chairman of the new Department of Cardiovascular Surgery at Stanford University School of Medicine.

Dr. Shumway's appointment and the establishment of the new department, both effective June 1, were announced Tuesday (April 9) by Dr. Clayton Rich, vice-president for medical affairs. They were approved earlier in the day by the University Board of Trustees.

The new department, formerly a division in the Department of Surgery, is believed to be the first of its kind in the United States.

"It is generally recognized that the Stanford program of cardiovascular surgery has for 15 years been among the most productive in the nation in research and education as well as patient care," Dr. Rich said.

"A remarkably dynamic and creative interaction among many diverse disciplines has occurred at this University as a direct consequence of a broadly conceived surgical approach to the investigation and treatment of heart disease.

"Granting departmental status to Cardiovascular Surgery will serve to maintain at Stanford a distinguished program in a new discipline which has reached scientific and academic maturity," he concluded.

Dr. Shumway, 51, is world reknowned for his work in cardiac transplantation and open-heart surgery. The heart transplant program at Stanford is the most active in the world, averaging one transplant per month. To date, 69 patients have received new hearts at Stanford; 24 are alive, one for four years and 11 months.

In cardiac surgery, Dr. Shumway's contributions have included the development of safer and more effective techniques for total surgical correction of "blue baby" heart defects, heart valve replacement, and correction of birth defects involving transposition of the heart's great vessels.

A firm believer that "the best arena for training good surgeons is the dog laboratory," he experimented with heart transplantation in dogs for nine years before undertaking his first human transplant on January 6, 1968. He credits much of his success in heart surgery and transplantation to persistent experimentation in the animal laboratory.

Dr. Shumway is the author or co-author of nearly 200 scientific publications and books.

A native of Kalamazoo, Michigan, he obtained his M.D. from Vanderbilt University in 1949, and his Ph.D. from University of Minnesota in 1956. He was a special trainee of the National Heart Institute at Minnesota from 1956-57, and joined the faculty at Stanford the following year.

Dr. Shumway and his wife have four children. They reside in Palo Alto.

In addition to Dr. Shumway, charter faculty members of the new department are Dr. Eugene Dong, Jr., associate professor of cardiovascular surgery, and Drs. Edward B. Stinson and Randall B. Griepp, assistant professors.

STANFORD--Two Stanford University dermatologists say injury to the skin often triggers attacks in patients with psoriasis.

"With poetic license, a psoriatic patient may be compared with a hemophiliac," write Drs. Eugene M. Farber and Paul H. Jacobs in the current issue of Cutis, a medical journal. "When cut, the hemophiliac bleeds, and the psoriatic develops a new lesion."

Several million persons suffer from the skin condition called psoriasis which produces reddened, scaly spots or patches, disability in many cases, and embarrassment, especially to women concerned about their skin.

"In a person with a lifelong disease such as psoriasis, prevention of injury to the skin is of the utmost importance," the dermatologists stressed.

Dr. Farber, who heads Stanford's department of dermatology, said that outbreaks of the skin condition in patients have been caused by such things as eyebrow plucking, chronic friction of the Achilles area from poorly fitted shoes, pressure of the wristwatch, a wallet rubbing against the hip, and tatoos.

"Even overenergetic manicuring produces injury to the matrix of the nail and is responsible for nail lesions," the dermatologist warned.

In addition, hair tints, sprays, vaccinations, skin tests, and insect bites have caused outbreaks, he said.

In the last decade, the dermatologists noted, light sensitivity of the skin has also increased in frequency because of widespread use of photosensitizing compounds in soaps, lotions, ointments and oral medications.

"Psoriatics," they added, "must be warned that photosensitizing compounds are deleterious and may result in the appearance of new lesions."

Dr. Farber cited a recent survey of 1,537 psoriatics conducted at Stanford under the auspices of the John A. Hartford Foundation of New York. The survey revealed the patients were frequently unaware of the effects of injury on their condition.

And more than half of the patients were found to have a history of attacks following injury to their skin, Dr. Farber said.

"The skin of the psoriatic patient has a characteristic reactivity when the disease is on the upswing," explained Dr. Farber. In an analysis of 100 patients with acute psoriasis, such outbreaks occured in 90 percent of the patients following injury.

The sensitivity of the psoriatic skin to injury was first described by Dr. Heinrich Koebner in 1876. It would help psoriatic patients to know that injury to their skin is as detrimental as the wrong kind of eating is to diabetics, the dermatologist said.

STANFORD--"The lag between the advanced state of technology and our ability to handle it at the human level indicates a pressing need for ethical guidelines in biology and medicine."

So says Dr. Ernle Young, acting chaplain of Stanford University Hospital. He is teaching the School of Medicine's first course on biomedical ethics, this spring quarter.

Young, who is also visiting assistant dean of Stanford Memorial Church, has been associated with Hospitals in Dallas, Texas and in his native Johannesburg, South Africa. It was his suggestion to offer such a course for Stanford medical students.

The course, which meets Wednesday evenings, includes theory as well as specific applications. "There seems to be a need for an ethical framework within which scientists and physicians may base their actions," explains Young. "The theoretical portion will provide a background that will help them in making concrete decisions."

Ethical issues at all stages of life will be examined. These include genetic manipulation, abortion, human experimentation and euthanasia.

Although the course is intended primarily for medical students, Young welcomes interaction with physicians, nurses and other Medical Center staff on the issues. He explains that because the field of biomedical ethics is still in the pioneering stages, everyone has much to learn.

Young belongs to a group of West Coast medical ethics teachers who meet periodically to share resources. Their diverse backgrounds--political, social, philosophical as well as theological--provide a rich pool of ideas.

He also expects to benefit from his own course. "I hope to open up the questions rather than provide the answers," the acting chaplain says," for there are no simple solutions in this area. At most, one can hope for a thorough ventilation." -more-

222--Medical Ethics

Medical students are enthusiastic about the course. "There seems to be a deficit of discussion on certain aspects of life throughout medical school training," says fifth year student Bill Hurlbut. "For instance, students should be able to sit and talk with others about death," he said.

Young's course is a valuable addition to the curriculum, according to Dr. Count Gibson, chairman of the Department of Family, Community and Preventive Medicine, which sponsors the course. "At a time when technological growth raises more ethical problems than solutions," Gibson notes, "it is important that the life scientists and ethicists collaborate to insure human welfare."

He adds that Young's willingness to develop a course on biomedical ethics is particularly welcome in view of his background. A Methodist minister in Johannesburg since 1956, Young went to Southern Methodist University in Dallas in 1967 to earn his Ph.D. in social and political ethics.

"I hoped to acquire some new means of entering into dialogue with the Dutch Reformed Church, which supports the South African government's policies of racial segregation (apartheid)," he says. However, when he returned to his country four years later, after receiving his degree, he found that no meaningful dialogue was possible. He left again in 1973 for "reasons of conscience."

He explains: "I cannot accept the situation in South Africa because it is incompatible with the Christian ethic of love; nor as a white English speaking person can I change it (the blacks themselves will have to). Under the circumstances, I feel it would be immoral to continue to benefit from the privileges which a white skin affords every South African."

Similar principles of conscience and humanity are involved in dealing with patients. "A patient must be treated as a whole person," Young says. "There are dimensions of personality that don't fit into the test tube or conform to laboratory values, and these spiritual aspects are as important as the physical ones."

STANFORD--"Sudden Death: The Problem and How to Prevent It," will be discussed Wednesday (April 3) in a public lecture at Stanford University by Dr. Donald C. Harrison, Irwin professor and chief of cardiology.

The lecture, free of charge, will begin at 8 p.m. in Memorial Auditorium. It concludes a series of four presentations by Stanford Medical School on recent advances in cardiology.

"Sudden cardiac death is now being recognized as one of the most important health problems in the country," Harrison says. "Nearly 300,000 Americans die each year of heart disturbances before they reach a hospital.

"Our efforts are aimed at finding better methods to identify high risk individuals and prevent some of these deaths."

Harrison is nationally known for his studies of various drugs used to treat life-threatening abnormal heart rhythms. He is also noted for the development of numerous monitoring and warning devices for high risk heart patients.

Under his direction, a Center for the Study of Sudden Death has been established at Stanford Medical School.

In recent years, he has pioneered in the application of computer science, physics, and engineering technology to cardiology. He is currently working with Stanford physicists on the perfection of a new device to measure blood flow and other cardiac functions by detection of the heart's magnetic signals.

A graduate of the Medical College of Alabama, Harrison received his professional training at Harvard and Stanford. He has been chief of cardiology at Stanford since 1967.

Harrison's presentation is the final Progress in Medicine lecture for the current academic year. The series will resume next fall.

STANFORD — Stanford University medical student Thomas Okarma has been selected as one of the first Luce Scholars, a group of 15 leading American students who will spend a year working and studying in Asia.

Okarma, due to graduate from Stanford Medical School next month, will work as a clinical pharmacologist at the University of Malaya Hospital in Malaysia.

He also will conduct research at the University's School of Medicine, where he plans to probe the mysteries of dengue fever, a tropical virus transmitted by mosquitoes. The hemorrhagic form of the fever has a particularly high mortality rate in Malaysian children.

The Luce Scholars program was established this year by the Henry Luce Foundation of New York. Each fall the program will send a group of outstanding American students to Asia for a year's experience in their field. The program excludes Asian scholars and focuses on students in professions such as physics, architecture, medicine, journalism, economics, and law.

Okarma, 28, said the year in Malaysia "will give me a chance to find out what tropical medicine is all about. There must be an incredible array of interesting things going on in Asian medicine which American doctors are unware of," he added.

Because he eventually plans to devote his career to clinical pharmacology, "exploring new ways of treating diseases," the assignment in Malaysia ties in very well with his long-range goals.

At the University of Malaya, Okarma hopes to determine why dengue fever is life-threatening in some instances and relatively benign, like a flu, in others.

The Malaysian government is particularly interested in encouraging research on the fever, since an epidemic is expected within the next few years, he said.

One of the workers in Okarma's lab may be his wife, Betsy, now a nurse at Stanford Hospital. A graduate of Stanford's School of Nursing in 1969, she also has earned a degree in art history from Stanford.

Okarma graduated from Dartmouth in 1968 and obtained a Ph.D. in pharmacology from Stanford in 1971 before entering medical school.

The Luce Scholars program appealed to him because he felt he needed a "creative year" before beginning his medical internship.

"Malaysia also struck us as the perfect place to be," he said. "English is spoken throughout the country, so I can teach and do research without a language barrier. There are numerous ethnic groups, each with their own religions and customs. For a foreigner, it's a marvelous place to learn about diverse groups of people."

Kuala Lumpur, where the University is located, is a very modern city, Okarma said. However, the native Aborigines and the Malaysian jungles are but 200 miles away.

The program begins in mid-September with a 10-day briefing at the Brookings Institution in Washington and a month-long orientation on Asian politics, culture and religion at the Chinese University in Hong Kong.

The Luce Scholars are selected from nominations submitted by a group of 60 participating colleges and universities around the country.

Okarma is the son of Mr. and Mrs. Theodore Okarma of Robbinsville, New Jersey.

EDITORS: Copies of Stanford M.D. available on request if not included with story.

STANFORD--The "Tuskegee" experiment is a prime example of white, educated clinical researchers exploiting nonwhite undereducated subjects for the benefit of middle-class Americans, a leading doctor of community medicine said Wednesday (May 29).

Dr. Count Gibson urged doctors to study the ethics of the issue because "only then we can be sure that we are not exploiting others for our own benefit."

In the Tuskegee syphilis study, 400-odd black men who had syphilis were left untreated 40 years so that the natural history of the disease could be studied.

The project was condemned by many researchers, doctors, civil rights groups, and a government advisory panel appointed to look into it on the ground that treatment was withheld from the study group. The study ended two years ago, but families of the subjects have initiated damage suits against Macon County, Ala., the Center for Disease Control, and the state health department.

Gibson, chairman of family, community and preventive medicine at Stanford University, addressed his remarks to articles published by two colleagues, Drs. Charles Barnett, emeritus professor of medicine at Stanford, and R. H. Kampmeier, editor of the Southern Medical Journal. Both defended the study on the grounds that treatment was never withheld deliberately.

Dr. Barnett published an article in Stanford M.D. maintaining that the cause of lack of treatment in syphilitics in those days was probably the intimidating nature of the therapy itself.

"At that time," he explained, "treatment consisted of courses of an arsphenamine in weekly doses for 6 to 10 weeks, alternating with weekly injections of mercury of bismuth for 10 to 15 weeks." This went on, he added, as long as two years.

There were severe and painful reactions to the therapy, he pointed out. "Patients with latent syphilis were well and took treatment only because they were told they must," Barnett stressed.

"When treatment made them sick and they felt better without it, they developed severe doubts about the wisdom of continuing." So, he feels, the untreated black Alabamans declined treatment after they had learned from friends what the "cure" was like.

But Gibson, writing in the current issue of Stanford M.D., argues that when effective treatment that improves prognosis is available--as he contends it was--ethical considerations demand that it be given.

Gibson responds with evidence that female syphilitics were not included in the study group and were intentionally treated to prevent possible transfer of the disease to offspring.

Another case of selective nontreatment cited by Gibson was the request in 1941-42 by the U.S. Public Health Service to the Selective Service Board. It asked that draftees in the study group be withheld treatment for syphilis because they were part of the study. A total of 256 men were denied medical aid as a result of this request, Gibson said.

- more -

In his article, Barnett defended the investigators for not providing penicillin treatment when it became available. He pointed out that penicillin injections are not guaranteed to prevent later manifestations of the disease. Several studies, he said, have shown that treatment probably reduces the incidence of later disease damage but have not shown that improvement is statistically significant.

Gibson said this line of reasoning is irrelevant. "The question obviously was not that of effecting cure but of halting any further microbial action," he pointed out.

Not surprisingly, Barnett disagreed. "The Tuskegee patients had lived long enough with their infections to show that almost all of them would never develop late-stage syphilis, and that penicillin treatment would have little effect on prognosis."

The Tuskegee study raised ethical questions of informed consent, Gibson said.

"It is extremely difficult if not impossible," he wrote, "for members of an oppressed group to give full and free consent to representatives of a dominant group, no matter how noble their intentions.

"The black rural residents of Macon County were as oppressed as if they had been in a physical prison. They did not have the autonomy that goes with education, good nutrition, a decent income, and political power.

"I do not feel we should benefit from therapeutic knowledge which depends on the exploitation of unfree human beings."

Theoretically, there could have been only one ethical way in which the "Tuskegee" experiment could have been carried out, Gibson added. The doctors could have inoculated themselves, isolated themselves when they were contagious, and could have followed their own progress..."

But the professor doubts that any syphilologist would have volunteered, given his knowledge of the disease.

Gibson criticized Kampmeier's sustained and intemperate attack on the news media for declaring the Tuskegee experiment "a horrible medical atrocity."

"In fairness," Gibson said, "I would like to point out that the medical profession never debated the ethics of the 'Tuskegee' research in its own journals despite the publication of a dozen studies on the topic over the years.

"The reporting in the press should be as much an indictment of the indifference of the medical profession as of the research itself."

He said he reviewed the Southern Medical Journal and "I cannot find a single reference to the lack of access to medical care by the Southern rural population, the segregation of black people in health care facilities until the Civil Rights Law of 1965, and the continuing lack of an adequate payment mechanism for medical care for poor people in Southern states."

STANFORD--The Speech and Language Clinic at Stanford will offer several group programs this summer for preschoolers, school age children, and adults with communications problems.

Preschool and school age programs will deal with articulation, language enrichment, visual-motor training, language-perceptual-motor training, and voice therapy. There will also be a summer program for deaf children, to improve their lipreading, oral language and sign language.

Ongoing parent observations are a part of these programs.

Adult programs include a stuttering group and voice therapy.

Each of the programs runs for six or eight weeks, meeting two to four times weekly for one-hour sessions.

Further information may be obtained from the Speech and Language Clinic at Stanford, 600 Willow Road, Palo Alto. Interested persons may call 497-6751.

The Clinic is a joint program of the Children's Hospital at Stanford and the Stanford Medical Center. The staff includes eight speech and language pathologists and one special education teacher, who handle about 8,000 patient visits per year.

Diagnosis and treatment is provided for all types of speech, language and voice disorders in patients of all ages.

STANFORD –

A technique for the production of new genetic species that may eventually lead to the synthesis of antibiotics or insulin by common bacteria, and possibly the correction of certain hereditary defects, has been reported by Stanford University and University of California scientists.

The technique involves the introduction of genetic material from one species into the cells of another.

Already it has been used by Stanford scientists to create functioning species of bacteria that do not exist in nature.

The scientists anticipate that within the next several years it will result in the construction of new biological species useful in medicine and agriculture.

Specific genes may be introduced into common bacteria for the synthesis of insulin and antibiotics, they indicated. Ultimately, specific genes may be inserted into the cells of patients to cure hereditary diseases, or inserted into plants to create desirable new types, they said.

Genes are biological units that transmit hereditary traits and govern the development of living cells.

Use of the technique to combine genes from unrelated bacteria was reported in the current issue of the *Proceedings of the National Academy of Sciences* (PNAS) by the Stanford researchers—Dr. Stanley N. Cohen, associate professor of medicine and head of the division of clinical pharmacology, and research assistant Annie C. Y. Chang.

"By constructing functional molecules in which genes from different species are joined, new types of bacteria are formed," Cohen said.

The basic method for constructing new functional genetic combinations was reported earlier by Cohen and Chang, in collaboration with Drs. Herbert W. Boyer and Robert B. Helling of the University of California, San Francisco.

Dr. Joshua Lederberg, Stanford's Nobel prize-winning geneticist, called the new technique "a major tool in genetic analysis."

"It does at the molecular level what cell fusion does at the cellular level, and cross-breeding does at the level of the entire organism," he said.

Lederberg believes the technique will have important applications in medical diagnosis, the study of the nature of cancer cells, and the study of gene control mechanisms or what turns a gene on and off.

"Finally," he said, "it may completely change the pharmaceutical industry's approach to making biological elements such as insulin and antibiotics."

(more)

cr 5/20/74

new genetic species 2-2-2

The Stanford and UC scientists, in another study, successfully inserted genetic material from an animal into bacteria, where it reproduced itself and functioned biologically. (That study, carried out with former Stanford student Dr. John Morrow and UC biochemist Howard Goodman, will appear in the May issue of PNAS.)

"The introduction of animal genes into bacteria provides a mechanism to study the organization and expression of hereditary material from higher organisms," Cohen said.

"Also, this technique provides a potential method for producing bacteria capable of synthesizing a wide variety of biological substances, such as antibiotics or insulin. It may also lead to bacteria capable of synthesizing chlorophyll or substituting for fertilizer in agriculture.

"Ultimately," he continued, "it may be used for correcting genetic defects."

Before this can be done, he said, scientists must develop better methods to isolate specifically desired genes from cells.

"Procedures are currently being developed at Stanford and elsewhere that may make it possible to select the genes required for these special functions within the next several years," Cohen said.

"However, certain other technical problems and important ethical considerations must also be resolved," he said.

The technique for constructing new genetic combinations is based on the ability of certain enzymes to cut DNA in a way which produces fragments having cohesive ends. These sticky ends are used to join DNA fragments from two sources.

(DNA or deoxyribonucleic acid is the molecule of heredity in living cells. It is the substance which gives the cell its hereditary instructions and perpetuates cell division.)

The essential units of DNA used in the experiments are known as plasmids. Plasmids are independent genetic elements within the bacterial cell capable of reproducing themselves independently of cellular reproduction.

DNA plasmids from bacteria have been joined in the test tube with genes from unrelated bacteria and from animal organisms. The newly-constructed DNA molecules are then inserted into bacteria treated with certain chemical agents.

Following the uptake of the DNA plasmids, the "transformed" bacteria acquire the genetic characteristics of both the parent molecules. In this way a new bacterial species is developed.

"This new species can reproduce to make other identical cells," Cohen said. "A single DNA plasmid molecule introduced into bacteria can be used to create many billions of molecules of this same new species."

Although the technique was first described only a few months ago, it is now being used by scientists around the world to introduce genes from various sources into bacteria, Cohen said.

STANFORD--State Senator George Moscone and national health policy strategist Dr. Paul Ellwood will be the featured speakers Thursday afternoon (May 16) at the opening session of a three-day health care symposium at Stanford, sponsored by the Stanford Medical Students Association.

The symposium, "Health Care: Problems and Prognoses," continues Friday and Saturday with panel discussions on the issues of health maintenance organizations (HMO's), regional health planning, and health manpower needs.

Ellwood's lecture, "How to Change the System," opens the meeting at 12 noon Thursday in Room M104 at the School of Medicine. Moscone's talk, "Issues in National Health Insurance Proposals," begins at 4 p.m. in Room M104.

The lectures are free of charge and open to the public.

Panel discussions are scheduled as follows: HMO's, 12 noon, Friday, Room M104; regional health planning, 1 p.m. Saturday, Room M104; and health manpower, 3 p.m. Saturday, Room M106.

The Stanford symposium is being held in conjunction with a meeting of the chapter officers of the Student American Medical Association's Western Region.

Ellwood, a Stanford Medical School alumnus (1953), is President of InterStudy, a Minneapolis-based organization engaged in social policy research. He is known as the architect of the Nixon administration's HMO strategy and a strong advocate of health care delivery reform.

In addition to HMO strategy, his studies have had a significant impact on national policy in comprehensive health planning, quality assurance, and health services research and development.

Before going into research full-time, Ellwood was a practicing physician in pediatric neurology and physical medicine and rehabilitation.

Moscone, California State Senate Majority Leader, is also chairman of the Senate Subcommittee on Nutrition and Human Needs. A former member of the San Francisco Board of Supervisors, he obtained his law degree from the University of California's Hastings College of Law in 1956.

For the past eight years, Moscone has represented California's Sixth Senate District, including southern San Francisco and northern San Mateo Counties. He has been Democratic Floor Leader since 1967.

Panel participants will be experts in the three discussion areas. Local panelists include Dr. William Fowkes, coordinator of the California Regional Medical Programs, Area III; Dr. Michael Dennis, director of Stanford's Primary Care Associate Program; and Richard Anderson, medical economist from the Kaiser Foundation Health Plan. ### Mailed Monday, May 13, 1974

STANFORD--Sleep studies and heart transplants will be among the topics discussed at the annual symposium of the General Clinical Research Center of Stanford University School of Medicine, Wednesday, May 15.

The community is invited to hear six investigators discuss their recent research from 12 noon to 5 p.m. in Room M106 at the Medical School.

The Center, on the third floor of the Hospital's east wing, is supported by a continuing grant from the National Institutes of Health, Division of Research Resources. Established in 1962, it provides a setting for clinical research and training at Stanford.

Specialized personnel and facilities are available in the area. Patient expenses are largely supported by the Center.

Dr. H. Keith H. Brodie, assistant professor of psychiatry and program director for the Center, will moderate the presentations.

The schedule is as follows: 12:00 noon, Dr. Clayton Rich, dean of the School of Medicine--Introduction; 12:15 p.m., Dr. William C. Dement, professor of psychiatry--"Clinical Studies of Sleepy People"; 1:00 p.m., Dr. John A Luetscher, professor of medicine--"Abnormal Adrenal Function and Hypertension"; 1:45 p.m., Dr. Stanley L. Schrier, professor of medicine--"Sideroblastic Anemias"; 2:45 p.m., Dr. Edward B. Stinson, assistant professor of surgery--"Why Stanford Continues Its Heart Transplant Program"; 3:30 p.m., Dr. Gerald M. Reaven, professor of medicine--"Role of Insulin Resistance in the Genesis of Hyperglycemia in Diabetes Mellitus"; 4:15 p.m., Dr. Thomas C. Merigan, professor of medicine--"Interferon and Other Anti-Virals in Varicella Zoster Infections."

ADVANCE FOR RELEASE THURSDAY, MAY 9, 1974

EDITORS: Release date set to coincide with publication of report in the *New England Journal of Medicine*

STANFORD — A Stanford University study reported Thursday, May 9, shows that physicians and their spouses receive as much or more surgery than other professionals and their relatives.

The study was undertaken by Dr. John P. Bunker and Dr. Byron W. Brown Jr., because it has been alleged that overuse of surgical services in the U.S. is often due to lack of consumer knowledge.

"Assuming that physicians possess such knowledge," Drs. Bunker and Brown wrote in the current issue of the *New England Journal of Medicine*, "we have examined their utilization of surgical services and compared it with that of lawyers, ministers and businessmen.

"Operation rates for physicians and their spouses were found to be as high as or higher than rates for other groups.

"Overall operation rates for physicians and for the other professional groups studied were estimated to be 25 or 30% higher than for the country as a whole."

Dr. Bunker concludes the physician as a patient and informed consumer places a high value on surgical care.

"The results presented suggest that as the public becomes more fully informed, the demand for surgical services will increase," he said.

Dr. Bunker, professor of anesthesia at the Stanford University School of Medicine, is currently on leave as a Guggenheim Fellow and visiting professor of preventive medicine at the Harvard Medical School. Dr. Brown is professor and head of the Stanford division of biostatistics.

Seven California groups took part in the study. They included male members of the Santa Clara County Medical Society and the Bar Association, Protestant ministers in Northern California, male graduates of Stanford Business School in Santa Clara and San Mateo Counties, women physicians practicing in California, and women members of the California Bar Association.

The surveys were carried out by mail questionnaire in 1972 and 1973. A total of 7,400 questionnaires was mailed, and response ranged from 75 to 83% for the several groups.

The questionnaire solicited information about a small number of commonly performed operations—appendix and gall bladder removal, repair of groin for hernia, thyroid gland and hemorrhoid removal, and hysterectomies.

Rates of these operations for male physicians and for the other three professional groups were closely similar for four of the five procedures, the Stanford study found. But the physicians' wives tended to have more operations than wives of the other three professional groups. (more)

The rate of hysterectomies among doctors' wives exceeded 50% by age 65, compared with the national rate of 33%.

"It is apparent that physicians and their wives place a high value on hysterectomy," Dr. Bunker said.

"Since more than half of the physicians' wives will have undergone hysterectomy by age 65, it can be assumed that many are performed for sterilization or convenience rather than for conventional medical indication.

"And it can be assumed that many would appear to be unnecessary. Yet, to the extent that hysterectomy was demanded by a knowledgeable consumer, one might reasonably argue that the operation did represent a perceived need."

Dr. Bunker said that with some caution, the results of the study can be used as a basis for predicting the impact of consumer education on demands for care in a medical system in which financial barriers are removed, as seems likely with National Health Insurance.

"We base this prediction on three assumptions," he said. "Physicans currently charged with defining norms and standards for optimal care for the general population (under the auspices of Professional Standards Review Organizations) can be expected to use the same liberal criteria they use in selecting care for themselves and for other physicians.

"The legislation of National Health Insurance will allow the public to translate these perceived needs freely into demands.

"And the need for surgical care for the population as a whole is greater than for the favored professional groups under study."

The research was supported by grants from The Robert Wood Johnson Foundation of Princeton, N.J., and the Commonwealth Fund of New York.

FOR IMMEDIATE RELEASE

STANFORD — Dr. Irvin Yalom, professor of psychiatry at the Stanford School of Medicine, has received the Edward A. Strecker Award for outstanding contributions in the care and treatment of patients.

The award, consisting of a certificate and an honorarium of $1,000, was announced Tuesday, May 7, at the meeting of the American Psychiatric Association in Philadelphia.

Dr. Yalom is currently on sabbatical leave at Oxford University in England. A graduate of Boston University Medical School, he is known for his studies in group therapy and the relationship of hormones to behavior. He is also known for his pioneering work in group counseling for dying patients and a program to explore group therapy techniques in the treatment of alcoholics.

He is coauthor of the widely acclaimed book *Encounter Groups: First Facts,* the first scientific study of the encounter movement.

The prize is offered annually by the Institute of Pennsylvania Hospital in memory of Dr. Edward A. Strecker, a distinguished psychiatrist and former president of the American Psychiatric Association.

STANFORD —

Education and Cultural Process: Toward an Anthropology of Education, edited by Stanford Anthropology Prof. George D. Spindler, was published this week by Holt, Rinehart, and Winston, New York.

Spindler, who contributed five major chapters to the work, pioneered the anthropological approach to teacher education when he edited the first volume in the series in 1955.

Thrust of the current book, he said, is an examination of how the theories, methods, and theoretical models of anthropology can be brought to bear upon educational problems and make a contribution to the training of teachers and the improvement of schools.

His articles examine built-in cultural biases of teachers, which stem from their own training and are not necessarily intentional, and how schools give their pupils a cultural identity.

He also looks into cultural sensitization techniques which can be incorporated into teacher training and for younger people in school.

Another chapter discusses how American colleges and universities have not acted as avenues to social and economic mobility, but rather to stabilize the *status quo.*

Spindler's two other books, *Transmission of American Culture* and *Education and Culture,* have often drawn on the collaborative abilities of his wife, Louise, who also holds a doctorate in anthropology.

Spindler and Prof. Robert Textor, professor of education and anthropology, together head a program called Anthropological Studies in Education.

Spindler and Textor are cofounders of the Council for Anthropology and Education, established in 1968. Textor is president-elect of the association.

EDITORS: A press conference with Dr. Zhores Medvedev has been scheduled for Friday, May 10 at 11:30 a.m. in Room M114 of the Stanford University School of Medicine.

STANFORD — Dr. Zhores A. Medvedev, a leading Russian gerontologist and geneticist and outspoken fighter for scientific freedom, exiled from his country last year, will lecture on "Dissent in the Soviet Union" Monday, May 13, on the Stanford campus.

His talk will be given at 8 p.m. in Dinkelspiel Auditorium. It is free and open to the public.

Dr. Medvedev will also lecture on "An Analysis of Longevity and the Human Lifespan" at 4 p.m. Friday, May 10, in Room M106 of the Stanford University Medical School

Currently on his first visit to the U.S., Dr. Medvedev will be the guest of Dr. Leonard Hayflick, Stanford medical microbiologist, a longtime friend and colleague

Dr. Medvedev was the first Russian intellectual to be confined in a mental institution, in the USSR in 1970, as a result of his outspoken views on Russian control of scientific thought and personal freedom.

The geneticist was barred from returning to Russia in January 1973 after he was allowed to leave the Soviet Union to undertake research in England

He is currently a visiting scientist conducting research on the biochemistry of aging at the Medical Research Council Laboratories in England. He was the originator, in the late 1950s, of what has grown into the "error theory of aging." His recent work deals with effects of redundancy in the genetic code on longevity.

Dr. Medvedev's latest book, *Ten Years after Ivan Denisovich,* has recently been published by Knopf in New York. The scientist is a close personal friend of Alexander Solzhenitsyn, and the book is a biography of the last 10 years of the life of Solzhenitsyn.

Dr. Medvedev came to public attention with publication of *The Rise and Fall of T. D. Lysenko* in 1962. Lysenko was the Russian geneticist who taught that animals and plants could be bred for characteristics acquired as a result of environmental treatments. Scientific thought holds that characteristics are acquired by hereditary mechanisms.

Lysenko's fame increased as Stalin favored his hypothesis. He became one of the leading geneticists in Russian, seriously setting back genetics in that country by his false doctrine.

Dr. Medvedev's book traced the rise of Lysenkoism to its eventual abandonment in 1965. The book was originally published in the Soviet underground, then smuggled out and published in the West.

Though Western scientists noted the book's value as a historical document, Dr. Medvedev became labeled by Soviet authorities as an undesirable dissenter.

In 1971 he was refused permission to present papers at the annual CIBA Foundation Lecture on Aging in London. In response he wrote *The Medvedev Papers,* highly critical of Soviet policy preventing scientists from freely exchanging information with Western colleagues and participating in international meetings outside the Soviet Union.

Publication of that material in the West led to his ouster as head of the Laboratory of Molecular Radiobiology at the Institute of Medical Radiology in Obninsk, near Moscow.

As a result of his 1970 imprisonment in a mental hospital, Dr. Medvedev and his brother, Roy, wrote *A Question of Madness.* This book was published in the West, and recounts his arrest, experiences in the mental hospital, and his release after a large letter-writing campaign both inside and outside Russia.

In 1972 Dr. Medvedev was reportedly "kidnapped" by Soviet authorities to prevent him from attending the International Gerontological Congress in Kiev. He was later released to return to his home.

Dr. Medvedev's treatement has raised concern among many U.S. scientists whether or not to promote and participate in exchanges with the USSR. Such action could damage West-Soviet relations.

The scientist has long-standing invitations to lecture and do research at Stanford, as well as at other U.S. institutions. However, Dr. Medvedev wants to return to the USSR and has expressed hope that his citizenship will be restored.

STANFORD--A study to determine more effective methods of controlling and preventing recurrent urinary tract infections in women is under way at Stanford University School of Medicine.

The project is supported by a $41,500 award from the Henry J. Kaiser Family Foundation, announced recently by Dr. Clayton Rich, dean of the Medical School, and Dr. Robert Glaser, president of the Foundation.

Urologic infections are extremely common in women, noted Dr. Thomas Stamey, chairman of the Division of Urology and head of the study. "As many as 20 percent of all women will experience urinary infections at some time during their life," he said. "Starting with an incidence of one percent in girls six years old, the rate increases to eight or 10 percent in women over 60.

Stamey stressed, however, that despite their prevalence in women, these infections pose no risk of serious kidney damage or complications for 95 percent of the patients.

The urologist plans to involve paramedical personnel in the project. Nurses and other paraprofessionals cannot make a diagnosis or precribe medication without consulting a physician, but they can learn to analyze and interpret urine cultures, Stamey explained.

"If they can be trained to assume some responsibility for routine care of patients with recurrent urinary infections, which constitute a large share of the urologist's caseload, we will be able to devote more time to patients with more serious renal problems," he said.

Over the next 18 months, women who have three or more episodes of urinary infection a year will be seen in the urology clinic at Stanford Hospital on Fridays. A nurse, supervised by Stamey, will help assess the patient's symptoms, test for infection and monitor the prescribed medication in routine cases.

The award reflects the continued interest of the Kaiser Family Foundation, according to Glaser, in supporting programs attempting to meet the health care needs of the nation. ###

STANFORD--An overall 9.0 percent increase in prices, effective immediately, was announced today (May 1) by Stanford University Hospital.

The bulk of the price change is reflected in the Hospital's daily room rates. Smaller increases will be made in the ancillary services (laboratory tests, drugs, x-rays, etc.) that make up half the average patient's bill, said Paul B. Hofmann, director of Stanford University Hospital and Clinics.

Hofmann said the increase is necessary to help align Hospital charges with operating costs, which have spiralled upward this year as suppliers were freed from price controls while hospitals were limited by Economic Stabilization Act regulations.

"We feel this is a fully justified adjustment," Hofmann said. "It is based only partially on anticipated cost increases. Primarily, it is an effort to recover costs we've already incurred this year due to inflation in the prices of food, utilities, linen, and medical supplies, as well as merit raises for employees."

Hofmann emphasized that Stanford's price increase is consistent with what the Hospital would have been permitted under Phase 4 guidelines, had they been continued.

For community patients, the daily room rates will now be $87.50 for medical and surgical wards. Semi-private rooms will be $95.00 and private rooms $107.00.

These figures represent increases of $9.50 to $11.50. Last July, the Hospital raised daily medical and surgical rates $9.00 to $11.00.

Obstetrical ward rates will now be $89.00 daily, with nursery rooms $62.50.

Hofmann pointed out that the daily room rate includes 24-hour nursing care, plus dietary, medical record, and other routine hospital services.

Medical and surgical room rates will be slightly higher for patients receiving services of interns and residents. Charges will also be higher for specialty units, such as Coronary Care.

FOR IMMEDIATE RELEASE

STANFORD –

With negotiations continuing, Stanford University Hospital took steps Tuesday to reduce elective admissions and surgeries in the event of a threatened nurses' strike.

The Committee for the Recognition of Nursing Achievements (CRONA), representing the Hospital's 714 registered nurses, announced it will strike Tuesday, July 2, if a contract is not signed by July 1.

Ms. Bonnie Johnson, CRONA president, said the nurses will supply minimal coverage for critical care areas, but would expect elective admissions to be cancelled so that limited personnel can be available to take care of seriously ill patients.

CRONA and the Hospital have been negotiating a new contract since March. The remaining issues are monetary, but neither side would give details today in their joint statement.

Both Ms. Johnson and Paul Hofmann, director of Stanford University Hospital and Clinics, said, "It's still our hope that we can avert a strike."

Hofmann added that Edward Allen, a state labor mediator, was joining the negotiations tonight at the request of the Hospital and the nurses.

In a letter to the medical staff, Dr. Thomas A. Gonda, medical director, said physicians have been asked not to admit elective patients who may need critical care after July 2.

FOR IMMEDIATE RELEASE
STANFORD –

A comprehensive care center for persons suffering spinal cord injuries will open Wednesday, June 19, at Palo Alto Veterans Administration Hospital.

The new center, serving veterans in the greater Northwest region, provides care for paralyzed patients immediately after injury, flying them, if necessary, directly to the center from as far north as Alaska.

Following initial treatment and rehabilitation, patients may be visited in their homes by medical staff. Continued outpatient service will be provided at the new facility for up to 100 patients per month.

Director of the extensive program at the VA is Dr. Inder Perkash, who holds a joint faculty appointment as both associate professor of surgery (rehabilitation) and clinical associate professor of surgery (urology) at Stanford University School of Medicine.

Dr. Perkash is noted for his work in returning paraplegics and quadriplegics to near normal functioning lives. (Paraplegia is paralysis of the lower half of the body, including both legs. Quadriplegia is paralysis from the neck down, including both arms and both legs.)

He has emphasized complete care of the patient, and in addition to staff physicians, several other specialists, including neurosurgeons, urologists, orthopedists, internists, and neurologists are available as consultants. Dr. Perkash has also brought together a staff of physical, educational, and occupational therapists, psychologists, and others.

Patients will also be seen by faculty and residents in training from Stanford School of Medicine.

The spinal cord is a bundle of nerve fibers and cells about 17 inches long, depending on the person's height, and connects the brain with the muscles, skin, and internal organs. The vertebrae are the 33 bones of the spinal column which surround and partially protect the spinal cord, which is soft and can be damaged by pressure from surrounding bones. How much of the body is paralyzed depends on where the injury occurs to the spinal cord.

Most spinal cord injury patients are victims of home, sport, or traffic accidents. Combat injuries cause a relatively small percentage of such injuries.

Spinal cord injuries used to be considered fatal or near terminal.

"More than 60% of World War II veterans with spinal cord injuries ultimately died of urinary tract infections and failures," says Dr. Perkash. "Today, the paraplegic can expect to live a near normal lifespan and have a relatively productive life."

One of the most critical factors in returning paralyzed patients to normal functioning lives, says Dr. Perkash, is reducing the rate of urinary infection.

As chief of the Houston Veterans Administration Hospital's spinal cord injury service prior to his current post, Dr. Perkash did extensive work in bladder rehabilitation through the use of intermittent catheterization, leading to bladder reflex without use of the catheter.

(A catheter is tubing passed through the urethra to drain the bladder. Until recently, the catheter was left in place for long periods of time in paralyzed patients.)

(more) cr 6/13/74

spinal cord injury center 2-2-2

Dr. Perkash's current studies indicate that as high as 98% of paraplegic and quadriplegic patients may become catheter-free, lowering their rate of catheter-related infections.

He has reported that catheter-free status had been achieved by 70 out of 76 paraplegic and quadriplegic patients at Houston who had catheters in place from a week to more than 10 years.

Patients are first taught to catheterize themselves. The frequency of catheterization is gradually reduced with increasing spontaneous voiding.

All the patients in the Houston study had infections when the transition to self-intermittent catheterization began. But 75% were rendered infection-free during hospitalization, and a further 66% were without infections on follow-up examinations.

The new center will have a "tremendous" effect on improved treatment for patients, says Dr. Thomas A. Stamey, head of urology and professor of surgery at Stanford.

Research work now under way at Stanford on neurogenic bladder and the neurophysiology of urinary tract problems will be enlarged at the VA facility.

"Each patient will receive a greater intensity of care and study," says Christos Constantinou, Stanford research associate in biomedical engineering and a consultant to the new center, who will be continuing his study of the early diagnosis of urinary tract changes in paralyzed patients.

Staff will also continually evaluate new mechanical devices to aid patients, such as a new pneumatic pressure suit a patient can wear to help him stand or walk.

There are motorized wheelchairs that can be controlled by the patient's chin, and devices that enable a patient who cannot speak to communicate by blowing or breathing techniques. Therapists are currently devising a way that a paralyzed patient may call his nurse by just a turn of his head when he cannot press a call button.

The facility will be one of the few centers to evaluate new "environmental control" devices which are being supplied from the VA Prosthetic Research Center in New York.

"Our aim," says Dr. Perkash, "is not to let the patient become dependent on the hospital, but to get him out on his own in the shortest time."

In Houston, paraplegic patients went home on an average of 10 weeks after injury, and quadriplegics after 17 weeks. Periodic outpatient care is necessary.

The new center consists of almost an entire building, completely remodeled at a cost of $700,000. It has many special features such as automatic sliding doors throughout, television sets that are both for recreation and serve as monitors for the nurses station, X-ray facilities, outpatient rooms, and 30 in-patient beds in modern rooms.

The facility offers activity-oriented indoor and outdoor recreation areas. There is also a complete "apartment" with kitchenette, bedroom, and living area that a patient will live in for a week or two to ease his transition to home life.

Physicians, social workers, and other staff can visit the patient in a home base program that begins July 1. Occupational therapists, for example, will rearrange kitchen utensils to levels the patient can reach, devise special ways to turn on faucets and answer telephones, and order ramps over steps where needed.

The Veterans Administration operates 16 spinal cord injury centers throughout the country. Dr. Perkash estimates that there are about a half million paraplegics and quadriplegics in the U.S., and approximately 1,900 hospital beds for veterans, and 500 such beds outside the VA system. He estimates that more than 10,000 new patients are added each year to those needing continuing outpatient care.

The Palo Alto VA is located on Stanford land four miles southwest of the Medical School. It is one of several facilities in the area closely affiliated with the University for purposes of patient care, clinical teaching experience for doctors in training, and research projects.

Dr. Perkash was trained in general surgery, urology, and rehabilitation medicine in India, England, and the U.S., with a special interest in paraplegic bladder control. In addition to serving as chief of the Houston service, he was associate professor of urology at Baylor College of Medicine.

STANFORD –

When Dr. Albert Stunkard joined the Department of Psychiatry as chairman last year, the courtyard of the psychiatry building was ivy and shrubs. Now, with his help, it has been transformed into a lovely Japanese garden.

The distinctive stone and sand gardens of Japan are designed to impart a "feeling of tranquility and restfulness," notes Stunkard, an Oriental garden enthusiast. "The idea seemed appropriate for the area used by patients waiting for treatment and by our staff."

Besides, the chairman adds, he wanted a Japanese garden. He missed the one he had at his home in Philadelphia. There he headed the Department of Psychiatry at the University of Pennsylvania before coming to Stanford. Here, he lives in a large apartment complex, where it is not possible to have his own garden.

The psychiatry courtyard, with its glass roof, looked like an ideal location. Since it would have been inappropriate for the Medical School to finance a Japanese garden, Stunkard arranged for one personally. He asked a professional gardener, Toshio Saburomaru of East Palo Alto, to work with him in designing the garden.

The art of Japanese gardening, nearly a thousand years old, has been strongly influenced by developments in Zen Buddhist monasteries. "It is based on an intricate philosophy of relationships in nature," explains Saburomaru, "but I just use my own imagination. There is no limit, other than budget, and it is surprising what can be done with a little space," he adds.

Psychiatry's garden is a microcosm of nature, a concept basic to the Japanese garden, according to Stunkard. The concrete walk which divides the garden is like a bridge over a stream. A stone structure on one side simulates a waterfall, the largest rock representing the chute. Smaller rocks suggest the tumbling water that gradually becomes a flowing stream of small pebbles. The ripples in the pebbles are the waves created as the water swirls around the smooth stones of the stream bed.

On either side of the pebbles are the banks of the stream with various plants: the small ferns and shrubs commonly found close to the water, then the taller bushes and trees of the forest beyond. The center of interest behind the waterfall is a pine tree, surrounded by smaller maples. On the other bank, the dominant tree is azara.

Like most Japanese gardens, this one has few flowers. "Evergreen trees and bushes are the general rule, with two or three flowering shrubs for color at different times of the year," explains Stunkard. This garden includes azaleas in bloom last month; rhododendrons now beginning to blossom; and two heavenly bamboo trees with white flowers and reddish leaves at opposite corners of the garden.

The ground cover of the garden is a fern-like plant called creeping mint. A group of medical students has begun a pool to predict when the entire area will be covered. They have placed bets on the exact date, and the one who comes closest will win the money in the pool.

Stunkard points out that Japanese gardens require little maintenance, and are particularly adaptable to small areas. Medical Center gardener Michael Tyers has already mastered the fine art of raking the pebbles into the wave-like ripples with a special rake, and cares for the garden with great devotion, he says. Saburomaru adds that in addition to watering and raking, only pruning is needed once or twice a year.

"This garden may not have the longevity of its centuries-old forebears," notes Stunkard, "yet its simple beauty may bring some of the peace and serenity characteristic of its predecessors to the patients and staff at Stanford today."

Maurice LeBlanc 327-4800, ext. 358

EDITORS: Story is released jointly by Children's Hospital at Stanford and Stanford University School of Medicine.

STANFORD — The first comprehensive center on the West Coast for design and fabrication of devices to fit needs of physically disabled children will be established at Chidren's Hospital at Stanford.

The center is believed to be one of the first in the U.S. for the research and development of rehabilitation aids for children with neuromuscular impairments.

It is funded in part by a matching grant of $800,000 from the Max C. Fleischmann Foundation of Reno, Nevada. The award was announced recently by Dr. M. Harry Jennison, executive and medical director of Children's Hospital, and Julius Bergen, chairman of the Fleischmann Foundation.

Children's Hospital is an independent institution affiliated with the Stanford University School of Medicine.

There are an estimated 40,000 physically disabled children in Northern California alone, said Dr. Eugene Bleck, clinical associate professor of surgery and chief of orthopedics and rehabilitation at Children's.

"The service will bring contemporary rehabilitation devices to patients throughout California and complement our orthopedic program," he added.

The rehabilitation engineering center is headed by Maurice LeBlanc, former staff engineer for the committee on prosthetics research and development of the National Academy of Sciences.

"Rehabilitation engineering is an umbrella term," explains LeBlanc, "which includes orthotics [braces], prosthetics [artificial limbs], and other products of advanced technology."

These include electric wheelchairs and mobility aids, communication devices for nonverbal children, and special assistive equipment for daily activities.

Children now obtain most of their equipment from community orthopedic appliance firms. "The difficulty," says Bleck, "is that the patient population has extremely varied disabilities requiring custom-built equipment for maay patients."

The new center will begin where these firms stop. "Our intention is not to duplicate or compete with private industry, but to supplement and improve," he emphasizes. "We want to develop different methods and create new devices to meet patient needs."

Scheduled for completion in October, the center will be housed in a modular building adjacent to Children's Hospital. It will be accessible to patients on wheelchairs and will include areas for actual construction and fitting of devices for patients.

Children referred by physicians will be examined by a team that includes orthopedic surgeons, physical and occupational therapists and rehabilitation engineers.

The service will be modeled after the Ontario Crippled Children's Centre in Toronto, Canada, the only one Bleck knows that is similar to what he envisions for Stanford. Orthotist Wallace Motloch is on leave of absence from Toronto to help set up the Children's Hospital Center. Physical therapist Fran Ford is patient coordinator.

Patients who can benefit from these rehabilitation aids include children with cerebral palsy, spinal deformities, muscular dystrophy, brittle bones (osteogenesis imperfecta), or crippling joint diseases. The device for each child will depend on that child's stage of development and particular problem—the extent of paralysis, deformity, or lack of neuromuscular control.

New approaches are rapidly replacing past practices, LeBlanc notes. The philosophy today is to provide physically disabled children with a life style that includes as normal development as possible. "Instead of giving children a brace and sending them home, we hope to offer them a wardrobe of devices, all tailored to their individual needs and in tune with their growth."

The Center is expected to cooperate with the Palo Alto Veterans Administration Hospital, where adult patients with spinal cord injuries have needs for mobility and communication similar to many of the physically handicapped children, LeBlanc said.

STANFORD--An historical play, "Cuahutemoc," describing the last days of Montezuma, last Aztec emperor of Mexico, will be presented in Dinkelspiel Auditorium on the Stanford University campus Saturday, July 27, at 7 p.m.

La Alianza Latina (Latin Alliance), advisory committee on Latin affairs at Stanford University Medical Center, is sponsoring the event, which is free and open to the public.

This is the first in what is hoped will be a series of cultural and art presentations of La Alianza Latina, which represents the Spanish-speaking employees of the Medical Center.

Alejandro Fontana, Hospital dietetics supervisor, will play the lead role of Cuahutemoc, Montezuma's son-in-law. A familiar actor and singer who has appeared in theater, movie and television productions, Fontana also is playwright of "Cuahutemoc." Other parts will be taken by professional community actors from the peninsula.

The Medical Center group has assisted with preparations for the production, including making all costumes by hand. These include elaborate Indian headdresses.

An aim of the group, according to Tony Rodriguez, manager of training and development at the Medical Center and officer of Alianza Latina, is to "develop an awareness in the Stanford community, to search out the old Latino culture and history and present it in plays and music."

STANFORD –

Stanford Medical School's successful physician's assistant program, jointly operated with Foothill College, will be broadened in September to include four other community colleges.

Dr. Michael Dennis of the Department of Surgery directs the overall program and supervises the clinical curriculum, while Foothill College provides the preclinical course work for the two-year program.

New funds for the expansion and decentralization of the program total $972,000, provided through HEW's Bureau of Health Manpower Resources and the California Committee on Regional Medical programs.

The community colleges selected to participate are located in Eureka, Redding, Modesto, and Salinas. Others will be added later.

The Stanford/Foothill program will continue as it has for the past two years, with about 20 students per class. The new grant will enable similar programs to be launched at the other community colleges and cooperating area hospitals.

Students in the program are called "primary care associates (PCA)." They receive an associate in science degree plus a certificate of completion from the community college they attend.

Purpose of the expansion is to recruit and train PCA's in the areas in which they live, then assigning them to serve with overburdened physicians in their communities or other medically underserved areas.

The PCA's assist the overworked and understaffed local M.D.'s by taking patient histories, giving physical examinations, doing simple laboratory analyses, providing minor therapeutic and diagnostic services, and offering patient counseling and education under the doctor's supervision.

"Current reports show," Dr. Dennis said, "that physicians are leaving rural areas for urban or suburban areas faster than they can be replaced, to say nothing of attrition due to death or retirement. The program hopes to retard this trend."

For example, he said, Merced County has only 29 general practitioners for a population which can go as high as 200,000 persons counting the annual influx of field workers. "Twenty-five additional physicians are needed there alone," he stressed.

The three-year grant, which extends through fiscal 1977, will provide for five PCA candidates among the four new community colleges for the first year, 10 the second year, and 15 for the third.

"In this way, California areas which show the greatest need for adequate medical care can be served quicker through PCA programs in their home areas," Dr. Dennis pointed out.

One physician in each area will be selected to serve as the clinical coordinator "to establish a firm link with existing family practice, residency programs, private practitioners, hospitals and clinics for rotation and preceptorship."

After the first year of basic preclinical course work, the second year stresses clinical training, primarily at Stanford Medical School and later at a local hospital as the programs develop, he said.

Recruiting standards are high. Of about 400 applications per year, the Stanford/Foothill program admits only about 20 students. Prerequisites include two years of "responsible direct patient contact," a hurdle which nurses and former medical corpsmen can easily clear; a high school diploma; college or high school courses in biology, chemistry, and physics; "documented evidence of ability to perform well at college level in health sciences"; and evidence of good health. Bilingual skills will be helpful, he added.

Before going to full employment, PCA graduates must pass the national certifying examination given by the National Board of Medical Examiners.

As in the past, the Stanford/Foothill PCA program will cooperate closely with the California Regional Medical programs through Dr. William C. Fowkes, area coordinator; with William Rogers, executive secretary of the California Academy of Family Practice, and with the five-county Health Services Educational Council.

Of the grant, nearly $345,000 will support the decentralization program over the three-year period, and about $43,000 is allocated for maintenance of "on the spot" education for each area program.

Of the first Stanford/Foothill PCA class, which graduated in 1973, nine of the 15 are now working in medically underserved areas of California. Of the 19 members of the PCA class of 1974, who were graduated in June, 16 intend to do the same.

STANFORD — Stanford University Hospital, standing as it does in the heartland of the Peninsula's electronics industry, is probably one of the most heavily monitored establishments of its kind.

Except for patients well on the road to recovery, it's hardly an exaggeration to say that there isn't a pulse beat that isn't monitored somewhere.

In the opinion of James McClure, the chief medical instrumentation engineer, it's probably the best monitored hospital in the state, if not the country.

McClure heads a staff of five, whose expertise is sought out by other hospitals and by manufacturers' representatives, who want them to run tests on their equipment, whether they sell it to Stanford or not.

His No. 1 priority, naturally, is the saving of life. Consequently the most heavily monitored areas are coronary care, intensive care, premature infants nursery, renal dialysis, and the like.

The next highest priority is life support equipment, electrocardiographs and electroencephalographs, pumps, and defibrillators—in addition to closed circuit TV for security services, VHF radio transmitters and receivers, down to checking the humidity and electrical conductivity in the operating rooms at least once a month.

In short, if it's a matter of electronics, McClure and his staff can handle it.

The staff consists of Bob Rich, bench technician and quality assurance man; Frank Evans, who holds a B.S. degree in physics and is a systems analysis technician; Joe Echols, preventive maintenance and trouble-shooter; Joe Bennett, TV repairman, who has had his own TV repair business in Redwood City for 25 years and works here part time (he takes courses in medical instrumentation at Foothill College); and Tom Poston, another technician who teaches at Hill School of Business in San Francisco and holds a first-class radio operator's license.

The staff is augmented by Charles A. Drace, mechanical engineer, Ralph Crawford, electrical project engineer, in charge of equipment installation, and other members of the Medical Center's support services team.

McClure himself spent 21 years in the Air Force. After serving in various categories, including a stint as a special investigator, he opted for Air Force training school in health sciences in 1958 and never looked back. He came to SUH in July 1972 while he was in the process of mustering out of the service.

Partly because of his military training and partly because he likes it that way, McClure's world is an orderly one. Every job is done by the book, carefully logged, records properly kept. Any piece of equipment which takes more than eight hours to fix goes to an outside repairman or back to the factory.

In a way, the recent nurses' strike was a blessing. It allowed McClure and his staff to get a little ahead in their maintenance work, a consummation devoutly to be wished in their line of work.

They also run a small consumers' research operation: No gear goes on duty without a thorough bench test, even if it's right out of the shipping box. If it doesn't measure up to SUH's high standards, back it goes.

"Our function," McClure emphasizes, "is to be as pleasant and supportive to the nurses and doctors as we can. Our job is to maintain life-saving and life-support equipment in top shape 24 hours a day, seven days a week, year-round, and we want the staff to know we're here to help."

In a small but efficient suite in the hospital basement, McClure and his staff can simulate the condition of any patient for equipment testing purposes. Many illnesses can be duplicated on a test machine, he explained.

He is especially proud of two things—a new manual he has prepared for the medical staff's benefit titled *Medical Instrumentation Operation,* a sort of how-to-do-it book for doctors and nurses.

The second thing of pride is the new monitoring setup in the hospital's East 2A Ward. This unit, plus the 30 "crash carts" for cardiac arrest stationed all over the hospital, has got to be the best in the country, he feels. "We can do things here that no other hospital can do," he says.

For that matter, he believes his new manual to be the only one of its kind in hospital use. McClure bases that judgment on the fact that many other hospitals want to copy it.

FOR IMMEDIATE RELEASE

STANFORD –

Dr. Henry E. Simmons, director of the Office of Professional Standards Review (PSRO) of the Department of Health, Education and Welfare, will speak at a colloquium on "Quality Assurance of Medical Care" at Stanford University School of Medicine on Monday, July 29. The meeting will be held in Room M108, 10 to 11:30 p.m.

Simmon's office is responsible for implementing the nationwide PSRO program. He is also HEW deputy assistant secretary for health.

The PSRO program was legislated by Congress for professional medical groups to maintain continuous review over the quality of care given Medicare and Medicaid patients. The reviews are expected to apply to virtually all hospital care if national health insurance becomes a reality.

Following the colloquium, Simmons will meet with Dr. Thomas Gonda, medical director of Stanford University Hospital, who recently assumed chairmanship of the Quality Assurance Program committee, and other Stanford faculty and administrators.

The visit to Stanford was arranged by the Health Services Administration program in the Department of Community and Preventive Medicine. The colloquium is open to interested members of the Stanford community and the public. –30– cr

FOR IMMEDIATE RELEASE

STANFORD –

Two nuclear physicists deeply involved in research on peaceful uses of the atom will be the next two speakers in the Stanford summer series of Aerospace Technology Seminars.

Dr. John L. Emmett, a Stanford alumnus who heads the Laser Fusion Division of the Lawrence Livermore Laboratory, will discuss his research Thursday afternoon, July 25. Lasers are considered one of the most promising means of achieving controlled nuclear fusion to provide an almost limitless source of energy.

Prof. Sidney D. Drell, deputy director of the Stanford Linear Accelerator Center (SLAC), will speak Thursday afternoon, Aug. 1, on the subject of "S.A.L.T. (Strategic Arms Limitation Talks)—Prospects and Progress."

Each will speak at 4:15 p.m. in Skilling Auditorium. The lectures are open to the public admission free.

Emmett was engaged in laser research for a number of years before taking his present post at Livermore. He previously worked at the Jet Propulsion Laboratory operated by his alma mater, Caltech, as well as at the Naval Research Laboratory in Washington and at Stanford Research Institute. He earned the Ph.D. in physics at Stanford in 1967.

Drell is a former member of the President's Science Advisory Committee, since abolished by President Nixon. He is a consultant to the U.S. Arms Control and Disarmament Agency, a fellow of the American Physical Society, and in 1972 received the E. O. Lawrence Memorial Award from the U.S. Atomic Energy Commission for research in theoretical physics. He is a member of the National Academy of Sciences and the American Academy of Arts and Sciences.

The lecture series is sponsored by Stanford's Department of Aeronautics and Astronautics. It is part of the 1974 ASEE-NASA Summer Faculty Institute chaired by Prof. Danial Bershader. –30– 7/22/74 cr

STANFORD — A committee of scientists has advised the National Academy of Sciences to call for a moratorium on research with hybrid or otherwise new viruses which may pose risks to scientists who work with them and to the population at large.

Scientists have recently developed techniques that permit joining together genetic material (DNA) from bacterial and animal cells or viral sources in the laboratory.

These experiments, experts believe, offer exciting potential both for studying how bacterial genes work and for alleviation of human health problems, including cancer.

"But there is serious concern that some of these artifical recombinant DNA molecules could prove biologically hazardous," Dr. Paul Berg, a Stanford University biochemistry professor, reported at a news conference in Washington, D.C., Thursday, July 18.

The scientists worry because some of the new kinds of molecules that can be created in the laboratory might escape accidentally and become established in the population at large. The effects of such exposure to man are unknown.

Berg was chairman of an 11-member group asked by the National Academy of Sciences-National Research Council to study the problem and recommend solutions. Appearing with Dr. David Baltimore of the Massachusetts Institute of Technology, Berg emphasized that lack of sufficient data makes it impossible to determine if a serious hazard actually exists.

But the scientists added, "Our concern for the possible unfortunate consequences of indiscriminate application of these techniques motivates us to urge all scientists working in this area to join us in agreeing not to initiate experiments until some resolution of the outstanding questions has been achieved."

The committee seeks a temporary ban on experiments which introduce new drug-resistant genes into bacterial strains that do not presently carry such information. An example of this would be altering the genes of the bacterium staphylococcus so that it becomes resistant to known antibiotics.

The ban also includes introducing genetic information from animal tumor virus DNA into bacterial cells.

The scientists urged their colleagues to proceed with caution in introducing animal cell DNAs into bacterial strains that can infect man. An example would be the bacterium *E. coli* that is common inhabitant of the human gut.

(more) 7/17/74 cr

"Since joining of any foreign DNA to a DNA replication system creates new recombinant DNA molecules whose biological properties cannot be predicted with certainty, such experiments should not be undertaken lightly," the committee said.

The committee also said that the National Institutes of Health should establish an advisory group to evaluate potential hazards of man-made DNA molecules, to develop procedures for minimizing their spread within human and other populations, and to develop guidelines for investigators in the field.

In addition, the group urged that an international meeting of scientists from all over the world should be convened early in the coming year to review scientific progress and to discuss ways for dealing with potential hazards.

Berg said he believes this is the first time in which scientists working in a particular area of research have called for a voluntary restraint in experimentation.

The general issue of hybrid DNA molecules so concerned Berg and other scientists involved in DNA research that a conference to discuss the subject was held at Asilomar, California, in 1973.

Similarly, a group of scientists at the Gordon Research Conference in June sent a letter to the National Academy of Sciences stating that such "hybrid molecules may prove hazardous to laboratory workers and the public," and suggested that a committee be set up to study the problem.

Besides Berg and Baltimore, other scientists on the committee were Herbert W. Boyer, University of California, San Francisco; Stanley N. Cohen, Ronald W. Davis, and David S. Hogness, Stanford University; Richard Roblin, Massachusetts General Hospital; James D. Watson, Cold Spring Harbor Laboratory; Sherman Weissman, Yale University; and Norton D. Zinder, Rockefeller Institute.

The committee report will be published simultaneously in the July 26 issues of *Science* and *Nature* magazines.

STANFORD--Emergency screening for poisoned patients will now be provided by a special drug laboratory at Stanford University School of Medicine.

Until now, blood and urine samples were sent to San Francisco for drug identification and analysis.

Called the Drug Assay Lab, the facility also helps monitor patients on certain therapeutic drugs to prevent toxicity and to help adjust dosage.

For a suspected drug overdose or poisoning, identification and timing are crucial. Laboratory personnel will be available 24 hours a day to screen and measure patient samples for the type and amount of substance involved. They will have the results within four hours, far less than a stat analysis from San Francisco would cost, according to Dr. Sumner Kalman, director of the laboratory.

"When poisoned patients are brought into the emergency room, we need information as soon as possible," says Dr. Michael Eliastam, director of emergency services. "Dealing with a laboratory in the City is more expensive and time consuming. A toxic screening here at the Medical Center is really needed."

It is difficult to determine the type of poisoning from clinical signs and symptoms alone, Eliastam continues. "Patients who are conscious may be reluctant to admit what they took, especially if it was an illegal narcotic. Some may not know what they had; street drugs can contain very strange mixtures."

Until the type and level of drug has been identified, no specific antidote can be administered. In the interim, measures are taken to stabilize patients and prevent their condition from worsening.

Followup tests to monitor drug amounts in seriously poisoned patients admitted to the Hospital are done at no extra charge. "The periodic analysis also offers the opportunity to study the effect and rate of excretion of potentially lethal drugs in humans, which of course could not be done any other way," Kalman notes.

The Drug Assay Lab, also provides blood and urine determinations of certain clinical drugs, particularly those with a small safety margin between a beneficial and dangerous dose. Drugs measured include those used in treating heart disease, epilepsy or other neurological disorders. Barbiturates and sedatives are also assayed.

- more -

222---Laboratory

"Every individual has a distinctive metabolic personality that determines how rapidly a drug is cleared from the body. There can be a ten-fold difference in the amount of drug required by different people in order to achieve the desired therapeutic effect," Kalman notes.

Dr. Dennis Clark, supervisor of the laboratory, explains the need for routine drug monitoring. A patient with epilepsy, for example, is taking a prescribed drug to control seizures, and the drug's effectiveness depends on that patient's metabolism. The drug could reach a toxic level in the bloodstream before it helps prevent attacks. Or the patient might have an unusually high tolerance for the drug and require more than the standard amount to achieve control.

"The important thing is to alert physicians to any drug levels which are either too high or too low in their patients so they can adjust dosages accordingly," Kalman stresses.

He says the services of the laboratory are available to physicians throughout the Bay Area, and he welcomes suggestions for new drugs to be included. At the request of Children's Hospital at Stanford, the laboratory is now developing a reliable assay for methotrexate, a potent anti-cancer drug used to treat children with leukemia.

Screening services such as Stanford's are relatively new, Kalman points out. Improvements in analytic techniques in recent years have made the identification and determination of specific materials easier and faster. The drugs are separated by gas chromatography, using assays developed primarily at the Stanford laboratory.

STANFORD--The Stanford University School of Medicine has received an unrestricted gift of $2 million from Mrs. Frances Nunnally Winzer of La Jolla, Calif., it was announced Monday (July 15).

The gift will be used to permit construction of a third floor in the Sherman Fairchild Center for the Neurosciences, to endow a professorship in cell biology, and to help complete the diagnostic and treatment laboratories in the Stanford University Hospital addition now under construction.

This is the second largest private gift received by the Medical School to date as part of the Campaign for Stanford.

Stanford University President Richard W. Lyman gratefully acknowledged the gift from Mrs. Winzer. "The University has long been the fortunate beneficiary of Mrs. Winzer's generosity," he said.

"Thanks to the Goodrich scholarships which she established in 1963 more than 200 students have been assisted financially to become practicing doctors. We are deeply indebted to her."

Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine, said "the gift allows unusual flexibility in using the funds where they really count in developing the programs of the School."

"Stanford is developing a strong, new program in the neurosciences," he added, "to study the brain and its relationship to neurological diseases and complex behavioral processes. The opportunity for important advances in this field are exceptional."

The Sherman Fairchild Center for the Neurosciences will house the departments of neurobiology, anatomy and physiology, laboratories for neurology and neuropharmacology, a bioengineering laboratory, and an auditorium. The Center should be completed in 1976.

-more-

222--Winzer Gift

A total of $1.5 million of Mrs. Winzer's gift will be used to add a third floor to the Fairchild Building being constructed with funds from the Fairchild Foundation.

Dr. Rich said $450,000 of the gift has been earmarked for the establishment of an endowed chair to be known as The Mrs. George A. Winzer Chair in Cell Biology. It will be held by the chairman of the Department of Anatomy and Physiology to be appointed in the near future.

The Winzer gift has attracted an additional $150,000 by an anonymous donor to fund the professorship fully, he noted.

Previous gifts have aided in the construction of the psychiatry building and laboratory for the study of the biological basis of behavior. The Frances N. Goodrich scholarships now assist 50 to 60 students annually.

Mrs. Winzer has been a major benefactor of Children's Hospital at Los Angeles and has also served as a member of its board of directors. She has been responsible for establishing five endowed chairs there in pediatrics, hematology, metabolism-endocrinology, pathology and nephrology.

STANFORD--Registered nurses began returning to work Friday (July 12) at Stanford University Hospital after voting overwhelmingly to approve a new two-year agreement ending their 11-day strike.

The Hospital is recalling its nurses as needed. It is expected that all of the nurses will be back within ten days as the Hospital builds back the case load of patients.

The vote of the members of CRONA (Committee for the Recognition of Nursing Achievements) in the Medical Center Thursday evening was 544 for acceptance of the tentative agreement and 15 against.

CRONA, which represents 714 registered nurses, had demanded a 16 percent wage increase and 1 percent in benefits during negotiations for a one-year contract. The Hospital's offer prior to the strike was 12 percent.

But a settlement for a two-year contract was hammered out Thursday morning at the end of 9-hour bargaining session assisted by Edward Allen of the State Mediation and Conciliation Service in San Francisco.

Principal provisions of the contract include a 15 percent wage increase this year for all registered nurses, and a second-year adjustment of 8.5 percent, effective July 1, 1975.

The settlement would provide a new salary range of $989-$1193 for an experienced staff nurse for the first year of the contract. The current range is $860-$1037.

Paul Hofmann, director of the Hospital and clinics, said the cost of the wage increase to the Hospital for the duration of the two-year contract is slightly less than 12 percent a year.

The 618-bed teaching hospital, normally filled with some 500 patients this time of the year, had 72 hospitalized patients Thursday morning.

About 30 nurses had staffed the Hospital's coronary care unit, intensive care unit, renal care unit, emergency room, and premature infants nursery. Half of them were CRONA nurses assigned by previous agreement to staff critical areas.

Most noncritically ill patients were discharged or transferred to other area hospitals. ###

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos 415: 321-5310 or 497-6911

STANFORD--Stanford University Hospital Friday (July 12) will put into effect new prices averaging an 11.5 percent overall increase for rooms and services such as laboratory, x-rays and drugs.

Daily room rates represent an increase between $12.50 and $15.50.

The new rates will be $100 for ward, $109 for semiprivate room, and $122.50 for a private room. Obstetrical ward rates will now be $97, up $8.

The new prices were approved by the Hospital's board of directors Thursday morning.

Paul Hofmann, director of the Hospital and clinics, said the rise reflects wage adjustments for non-contractual employees, anticipated increases for nurses and higher costs in the Hospital's general operation.

"Wage increases this year were the highest in recent years in response to the rising market for hospital personnel in the Bay Area and nationwide," he said.

The Hospital increased its prices an overall 9 percent in May to give employees deferred wage increases and to cover costs already incurred.

Prior to May, Hofmann said, hospitals were under wage and price controls while most parts of the economy were allowed to raise their prices. As a result funds needed for equipment replacement, new projects, and salary adjustments have been depleted.

However, Stanford's rates are somewhat lower than those of a comparable university teaching hospital such as the University of California in San Francisco. Rates there are $114 for a ward, $119 for a semiprivate room and $122 for a private room.

Hofmann said the daily room rate includes 24-hour nursing care, plus dietary, medical record, and other routine hospital services.

Medical and surgical room rates will be slightly higher for patients receiving services of interns and residents. Charges will also be higher for specialty units, such as coronary care.

More than 99 percent of the Hospital's revenue comes from patient care services. The Hospital has no tax support or endowment income.

STANFORD--Mass screening for eye disease through television will be investigated by ophthalmologists at Stanford University School of Medicine.

Drs. A. Ralph Rosenthal, head of the Division of Ophthalmology and Milton Flocks, clinical associate professor of ophthalmology, will study the feasibility of utilizing television to detect vision impairment and visual field defects.

"We plan to test the responses of adults to a brief television or videotape sequence," said Dr. Rosenthal. "This procedure could prove effective for large scale detection of certain ophthalmological problems, particularly visual field defects which are often associated with glaucoma, retinal degeneration, brain tumors and certain other disorders of the central nervous system."

The work will be supported initially by a one-year award of $5000 from the National Society for the Prevention of Blindness. Effective August 1, it was announced recently by Frederic Weisenheimer, executive director of the Northern California Society for the Prevention of Blindness, and Dr. Clayton Rich, dean of the School of Medicine.

A reliable mass screening technique can be extremely valuable, according to Rosenthal. There are many individuals throughout the world who have serious visual field defects and are unaware of them. Identification of these individuals and discovery of the cause of their visual defects could save many of them from blindness and some of them from an early death.

Once developed, the procedure could be used in areas and countries where for economic or other reasons people do not receive regular eye examinations.

STANFORD--Scientists at Stanford University School of Medicine have found that a tumor produced in mice may serve as a model for studying little understood brain tumors in children.

The research report received an award for the best paper in experimental neuropathology presented at the 50th annual meeting of the American Association of Neuropathologists in Boston.

The tumor was found to correspond to different types of brain tumors in children. About half of the intracranial tumors in childhood are of the embryonal type found in the mouse strain.

The scientists, including a second year medical student, have transferred this particular tumor to succeeding mice within a certain inbred strain, thus establishing a tumor bank that makes continued studies possible. The original tumor was developed by Dr. L.C.Stevens at the Jackson Laboratory, Bar Harbor, Maine.

The mouse tumor showed 80 to 90 percent nervous system tissue. It also exhibits various stages of maturity of the nervous system, and may be used to study how the nervous system matures normally in man.

Dr. Mary M. Herman, who directed the research project, is assistant professor of pathology (neuropathology). Presenting the paper in Boston was Scott R. Vandenberg, second year Stanford medical student. Researchers also included Dr. Amico Bignami, associate professor of pathology (neuropathology), and Drs. A.M.Spence, J.C.Sipe and S. Ludwin, trainees in the graduate neuropathology training program.

This is the second time that a group of workers from Stanford was selected for the award, and the second time in the history of the award that a medical student was a leader in the research effort.

Now that the tumor has been characterized in the lab, further work will begin on isolating its cellular components and identifying them using biochemical and antigenic markers, according to Dr. Herman.

The work was supported by an American Cancer Society Institutional Grant, and a grant from the Stanford University Research Development Fund awarded to Dr. Herman.

STANFORD--Dr. Robert A. Chase, Emile Holman professor of surgery and chairman of the Department of Surgery at the Stanford University School of Medicine, has resigned to become president and director of the National Board of Medical Examiners.

Chase's appointment was announced Monday (July 8) in Philadelphia by Dr. Jack D. Myers, chairman of the board.

The 51-year-old surgeon will succeed Dr. John P. Hubbard, who is retiring after 25 years as chief executive of the board. Chase's appointment becomes effective in November.

Myers said, "Dr. Chase will assume the presidency at a critical juncture in the National Board's continuing search for better ways to measure the clinical competence of physicians throughout their professional careers."

Chase, an internationally known surgeon who specializes in reconstructive surgery of the hand, is also well known for his teaching and leadership in medical curriculum innovations, residency training, medical licensure, and continuing medical education.

He has been chairman of the department of surgery at Stanford since 1963 and, in addition, has served as acting chairman of the anatomy department for the past year.

His interest in teaching will be continued through an affiliation with the School of Medicine of the University of Pennsylvania where he will also serve as a consultant in surgery.

Chase, a native of Keene, N.H., is a graduate of the University of New Hampshire (1945) and Yale University School of Medicine (1947).

Prior to coming to Stanford, he was an associate professor at Yale University School of Medicine.

He is a member of the Institute of Medicine of the National Academy of Sciences, past chairman of the surgical council of the American Board of Medical Specialties, and the international relations and graduate education committees of the American College of Surgeons.

The National Board of Medical Examiners, founded in 1915, is a voluntary, nongovernmental examining agency concerned with maintaining high standards of medical education and in testing physicians' qualifications for professional practice.

The Board's examinations are now taken by medical students throughout the United States. Medical schools also use National Board examinations as a source of external evaluation of their students' progress.

FOR IMMEDIATE RELEASE

STANFORD –

Bedrooms for people who can't sleep will be provided this summer through a Stanford University project.

A specially equipped Stanford dormitory, dubbed Hotel Insomnia, has been set up to help researchers learn more about why people can't sleep.

"Insomnia affects some 20 million people in this country," said Dr. William C. Dement, director of the Sleep Disorders Clinic and head of the project. "There may well be 100 entirely different causes of troubled sleep," he continued, "but until we have the opportunity to study hundreds of sufferers, we just won't know."

Recent studies have already revealed several causes of insomnia, previously unsuspected by patients or their physicians. For example, there is a peculiar condition called nocturnal myoclonus in which the muscles of the anterior calf twitch continuously, but only during sleep. Nearly one-fourth of the insomniacs tested in the past few months at Stanford exhibited this symptom, which eventually arouses the sleeper.

Another problem, Dement continues, is sleep apnea insomnia. Certain patients actually stop breathing for repeated intervals and must awaken to resume normal respiration. A few insomnia sufferers have an increasing tendency to gag while asleep. Others just keep moving throughout their sleep.

These and other causes can only be identified by extensive observation and brain wave analysis, in both insomniacs and normal subjects. "Once the cause of insomnia can be detected in an individual, it may be treated to reduce or eliminate the sleeper's problem."

He stressed that the Stanford study provides an opportunity for volunteers to have their insomnia expertly evaluated. All costs involved in clinically processing each volunteer are covered by private sources.

Subjects will be followed at no charge for several nights while they sleep. All physiological functions will be carefully monitored on one of Hotel Insomnia's 20 electroencephalograph machines. Highly trained sleep laboratory technicians are on duty constantly, and a physician is on call at all times. Such a comprehensive evaluation would cost over $2000 in a hospital setting, according to Dement. He notes that former participants enjoyed being part of the insomnia project.

Volunteers are asked to call Sleep Disorders Clinic, (415) 497-1128 as soon as possible.

STANFORD--More than 700 Stanford University Hospital nurses went on strike Tuesday morning in the first walkout of its kind in the Medical Center's history.

The walkout, threatened for a week by members of CRONA (Committee for the Recognition of Nursing Achievements), went into effect after the latest salary offer by the Hospital was turned down.

CRONA seeks a 16 percent salary increase plus one percent in benefits. Hospital management first offered a 7.9 percent raise, then a 9 percent increase, but CRONA rejected all offers, including a 12 percent offer voted down Monday. CRONA said that the salary is needed to be competitive in the Bay Area nurses' market. "In order to maintain our high level of patient care," CRONA said, "we need to attract and keep the best quality of nurses possible."

The two original offers, Hospital management said, were based on prevailing Bay Area wage patterns for nurses. The 12 percent offer reflected the recent settlement involving the 42 Affiliated, Associated and Kaiser hospitals.

The second or 9 percent offer was comparable to wages paid at the University of California Hospital in San Francisco, following a request for parity with that institution by CRONA.

As of early Tuesday, 38 nurses reported for duty out of a normal complement of 146 per shift. Of the 38, nineteen were on strike but were serving in critical areas as previously agreed to by the nurses' association, including intensive care, emergency service, premature infants, coronary care, renal care, and certain operating rooms.

Stanford University's outpatient clinics are not affected.

Both sides said they will meet Friday for further talks.

In the meantime, patient load at the Stanford Hospital has been reduced from more than 500 normally to 185 patients, and this was expected to be reduced to 130 as soon as possible.

All but critically ill patients have been discharged or transferred to other area hospitals.
CRONA has stood firm on its demand for a 16 percent raise plus a one percent increase in benefits.
Hospital management said it was prepared to accept final and binding arbitration of the dispute.
Edward Allen, a mediator from the State Labor Conciliation Service, has been meeting with both sides for a week attempting to work out a settlement.
CRONA's contract with the Hospital expired at midnight Sunday, June 30.

STANFORD--A new proposal for a salary increase for registered nurses will be submitted to a vote Monday (July 1), Stanford University Hospital officials and negotiators for the nurses announced Sunday night.

Details were not disclosed.

Negotiations have been under way since March 20 on a new contract for Stanford registered nurses which expires tonight (June 30). Salary is the major issue.

The Committee for the Recognition of Nursing Achievements (CRONA), representing the hospital's 714 registered nurses, announced last week that nurses would strike July 2 if their contract demands are not met by Monday.

In anticipation of the possible strike, the Hospital took steps to reduce elective admissions and surgeries. CRONA President Bonnie Johnson said nurses have offered to supply minimal coverage in critical areas but would expect elective admissions to be cancelled.

During the weekend, many patients were discharged by their physicians or transferred to other hospitals. The Hospital census on Sunday night was 300. Stanford Hospital has 618 licensed beds.

Publicly both Ms. Johnson and Paul Hofmann, director of the Hospital and Clinics, expressed their hope that a strike can be averted. A state labor mediator, Edward Allen, has joined the negotiations and met with both groups during the weekend.

In the event of strike, Stanford Hospital plans to care for only the number of patients for whom a high quality of care can be provided with available personnel. Areas which will be open include the premature infants nurseries, intensive care unit, coronary care unit, emergency room, and certain operating rooms, Hofmann said.

Hospitals which will receive transfer patients include Kaiser and Sequoia Hospitals in Redwood City, the Palo Alto Veterans Administration Hospital in Palo Alto, El Camino Hospital in Mountain View and Santa Clara Valley Medical Center in San Jose.

STANFORD--Although millions of Americans may suffer with what is commonly referred to as "tennis elbow," they may also be unknowingly aiding bone growth. Specifically, bone in the playing arm.

This is the conclusion of research directed by Dr. James D. Priest, an orthopedic surgery resident at Stanford Medical Center.

Priest says gains are finally being made toward understanding this dreaded malady believed to afflict about one-half of the nation's estimated 20 million tennis players, amateur and professional alike.

Studies have shown tennis players to have a significant increase in bone and muscle tissue in the elbow area, according to Priest. Furthermore, a study by Priest and Dr. Henry H. Jones, professor of radiology at Stanford Medical School, also shows an average increase of about one-third in the size of humeral bone (bone from the shoulder to the elbow) among tennis players. In one player studied the bone volume nearly doubled.

Tennis elbow is usually caused when the elbow is subjected to abnormal motion and stress, similar to what is required in the game of tennis.

In two recent studies, one involving 84 professional tennis players (54 men and 30 women) and another in which 231 amateur players at the Palo Alto Tennis Club were questioned, Priest found that approximately one-half have had tennis elbow at one time or another.

In addition, he discovered that among the professional players about one-third had "major symptoms" about the playing elbow, including lateral humeral epicondylitis (tennis elbow). However, at the same time, Priest found a significant increase in size of the humeral bone among the professionals.

Priest is quick to point out that although tennis elbow is automatically associated with the tennis game it is not limited to players of that sport. Elbow injuries also strike baseball pitchers, javelin throwers and others. Industrial workers using hand tools are also good candidates for tennis elbow as are dentists and other technical and professional people.

"If a dentist or surgeon develops tennis elbow he may not be able to use his arm effectively or painlessly for up to a year," Priest said. "Tennis elbow goes far beyond athletics; it is a public health problem."

- more -

22--Tennis Elbow

For those who get tennis elbow Priest estimates the discomfort to last between three months and one year. He noted that an extreme case would even prevent a person from lifting a teacup with his playing arm.

A tennis buff himself, Priest said he hopes his studies will eventually lead to a cure. He said this might include equipment changes in the game itself, but further studies would be needed to determine if this is necessary.

Although he says he falls into that "lucky half" not yet touched by sore elbows, Priest notes that those not so fortunate are seeking cures now. These often include an elbow band for the forearm and steroid injections to ease the pain. But he says none of the oral medications or other treatments have actually been proven successful.

Significantly, in his studies with the Palo Alto tennis players, Priest discovered that the stroke most often associated with pain was the backhand. He noted that nearly all of those with elbow problems use a one-handed backhand swing on the court. Conversely, nine players who said they use a two-handed backhand did not report any elbow pain.

Priest, who was also an engineering postdoctoral research fellow (1972-73) at Stanford's Department of Applied Mechanics, believes his work on tennis elbow has opened new avenues of research into bone growth, as well as into shoulder and spine problems associated with sports. Priest noted that half of the pro tennis players interviewed complained of shoulder pain (in addition to elbow pain).

In all of his work Priest did not find any significant differences between right and left handed players. However, he said there was a high incidence of elbow pain among tennis players who compete regularly over the years as opposed to those who take up rackets on weekends.

Priest stressed that he hopes his work will eventually help older people suffering with disuse osteoporosis, or "brittle bones." "If we can correlate the incidence of brittle bones with the lack of exercise among older persons this may be one of the more important ramifications of the study," he concluded.

Priest was assisted in his study of the professional tennis players by Carol Jo Chinn, physical therapist, and by Barbara E. Kent, assistant professor and clinical co-ordinator in the Division of Physical Therapy, Stanford.

STANFORD--A new training program designed to improve emergency care delivery on the peninsula is being initiated by the Stanford University Medical Center.

Twenty-two firemen--12 from Palo Alto and 10 from South San Francisco--will begin 12 weeks of training Sept. 3 in the Department of Emergency Services at Stanford to become qualified paramedics, or emergency medical technicians.

Dr. Michael Eliastam, director of emergency services at Stanford Hospital, is in charge of the program which will tutor the firemen in special emergency medical procedures.

The paramedics will be trained to treat a patient on the scene while keeping contact by radio with a physician or nurse at the Medical Center. This contact will continue until the patient arrives at a hospital.

However, the paramedics unit will not transport the patient, although one paramedic may accompany him on the ride to the hospital. The other member of the two-man paramedic team will follow the ambulance in his own emergency van in case the patient should develop complications along the way.

Switchboard operators at police and fire stations will summon the paramedics when they are needed in a certain emergency. Although specially trained, the paramedics will not replace ambulance attendants on emergency runs. Instead, they will be called first to provide emergency medical care.

To date, Campbell is the only other Northern California city with trained paramedics ready for field service. In Southern California, however, paramedics (firemen) have been in operation in San Diego and Los Angeles for several years.

Initially, the Stanford University campus will be covered by the Palo Alto paramedics. Barron Park will also be covered, but not other adjacent towns and cities.

The paramedics will receive 200 hours of lecture and 300 hours of clinical work from Stanford physicians and nurses. The training will be supervised by Charlene Souza, RN, emergency services training co-ordinator.

Among the most enthusiastic supporters of the paramedic program is Palo Alto Fire Chief William Korff, who is excited over the prospect of having an emergency medical team. "This (program) has been badly needed and we should have had it years ago," he said, "it should be an outstanding program for the City of Palo Alto, Stanford University and the nearby area."

Dr. Eliastam hopes the program will expand so that the Stanford community will ultimately have its own paramedic unit. "The Palo Alto system will probably be deluged by Palo Alto calls alone," he explained, "therefore Stanford should eventually have its own system." Dr. Eliastam said the Menlo Park Fire District (like Stanford) should also eventually have its own group of paramedics (the Menlo Park district includes Menlo Park, Woodside, Atherton and East Palo Alto).

- more -

22--Paramedics

The City of Palo Alto has budgeted $84,541 for the first operational year of the program, according to Korff, including $30,000 for an emergency van to be used by the paramedics. The City of South San Francisco has likewise allocated funding for a van as well as for training.

Dr. Eliastam noted that although he wants Stanford and other local fire departments to have paramedics on their staffs he is uncertain whether additional groups will be trained at Stanford in the near future. However, the program may also be open to private ambulance companies.

The paramedics will keep in contact with the hospital during their field operations and their emergency van will carry various specialized equipment, including a cardiac monitoring device. The two-man teams will be on call on a rotating basis working out of Palo Alto's Mayfield fire station.

For the patient the paramedic service will not be free. The Palo Alto City Council has set a flat $40 fee for each patient. In addition, the patient will be responsible for ambulance transport and hospital charges. The council imposed the fee to reduce what it termed "frivolous" or unnecessary calls.

Once the firemen have completed the training and final testing, including oral examinations, they will be certified by the county public health department to serve as paramedics.

Campbell's eight trained firemen/paramedics are expected to begin their operations next month. Stanford's emergency staff will provide the radio supervision of their field work. However, the Campbell ambulances will continue to transport their patients to local hospitals.

STANFORD--Families of critically-ill patients often must spend long hours waiting in the hospital for a brief bedside visit. They must confer with doctors in busy hospital corridors.

A Menlo Park couple, both former Stanford University Hospital patients, now hope to make the waiting easier by providing a comfortable, private refuge for families of the very ill.

Mr. and Mrs. W. Drew Leonard plan a unique meditation room and lounge for the new Stanford Hospital wing which is now under construction.

During the last year, both spent long hours in the Hospital's corridor waiting area outside the intensive care unit, as each took a turn as patient. Leonard was hospitalized with a heart attack. Shortly afterward, Mrs. Leonard underwent surgery which revealed cancer of the liver. She is currently undergoing chemotherapy treatment.

During these times, each became aware of the need for a comfortable place where families and close friends can spend their waiting hours, and where a physician can talk privately about the prognosis for a critically-ill patient.

Space has been set aside for an enclosed waiting room in the $9.1 million Hospital expansion project. The Leonards would like to see it designed as a small meditation room and a larger adjoining lounge, located near the entrance to the emergency room and adjacent to the intensive care unit.

Although the space has been designated, the interior design and furnishings of the rooms must be financed. So the Leonards began writing to many friends and acquainfances asking for support of their project.

Mrs. Leonard, a sustaining member of the Peninsula Volunteers and a Stanford Hospital Auxiliary volunteer, is now confined to her home by her illness, but she enthusiastically shows swatches of carpeting and unrolls blueprints.

"It has taken away the blow from my illness to know I can do something to help patients and their families. I feel blessed to have this project..."

She does not plan an antiseptic, institutional waiting room. She envisions soft carpeting, stained glass windows that are the work of a recognized artist, religious books, a game table, sofas and chairs--an area designed by professional decorators "as a place of comfort and privacy."

Particularly, she plans to loan to Stanford Hospital several rare 1400-year-old Peruvian "Huacos," pottery pieces, to be exhibited in the meditation room and lounge.

Mrs. Leonard visualizes the stained glass window as one of the most important features of the meditation room, "providing consolation to those in distress."

To date, more than $12,000 has been donated. It is estimated that costs, however, may go as high as $25,000 or more, so the campaign is continuing for what Mrs. Leonard calls "this essential human environment."

Leonard is a vice president of Utah International, and graduate of the Stanford School of Business. The Leonards have two daughters, Lisa and Mrs. Robert Burnett of New Jersey.

STANFORD--Dr. Norman Kretchmer, Harold K. Faber Professor of Pediatrics at Stanford University School of Medicine, has been named director of the National Institute of Child Health and Human Development (NICHD) of the National Institutes of Health (NIH).

His appointment was announced today (September 27) in Bethesda, Maryland, by Dr. Robert S. Stone, director of the NIH. It was effective September 1.

The 51-year old pediatrician and biochemist was on sabbatical leave from Stanford as a Guggenheim Fellow this year, and served as consultant to the office of the NIH director. In his new position, he succeeds Dr. Gilbert Woodside, acting director of the NICHD for over a year.

Former chairman of the Medical School's Department of Pediatrics, Kretchmer is internationally known for his research in developmental nutrition and biology. His studies on differences in the nutritional needs of infants and adults have helped physicians assess the importance of proper diet in childhood.

In addition to his administrative responsibilities at the NICHD, Kretchmer will continue to study the biochemical basis for certain hereditary and metabolic diseases of infants. He will also be clinical professor of pediatrics at Howard University and consultant to the U.S. Navy at Bethesda National Naval Hospital.

Kretchmer also contributed to patient care and education at Stanford. Under his leadership from 1959 to 1969, the pediatric department broadened the scope of its clinical and scientific programs. When he relinquished his executive duties, Kretchmer headed the committee responsible for Stanford University's undergraduate human biology major.

A native of New York City, Kretchmer received his B.S. degree from Cornell University in 1944. He was awarded a Ph.D. in physiological chemistry from the University of Minnesota in 1947 and an M.D. from State University of New York in 1952.

Before coming to Stanford in 1959, he was associate professor of pediatrics at Cornell University.

Kretchmer is a member of the American Academy of Pediatrics, president of the International Organization for the Study of Human Development and consultant to the World Health Organization. He is also past chairman of the Medical Advisory Board of the Foundation for International Health and past president of the Society for Pediatric Research.

The NICHD supports and coordinates research related to population, maternal and child health, and human development and growth. It is one of 10 component institutes of the NIH, the principal federal agency responsible for biomedical research.

FOR IMMEDIATE RELEASE
STANFORD –

Stanford University Medical Center, already facing belt-tightening to control operating expenses, will have to spend more money to complete the Stage I expansion of Stanford University Hospital.

The University Board of Trustees has approved a revised budget of $12,600,000 for the project.

This increase, from the formerly approved budget of $9,560,000, is primarily due to changes in design made necessary by the interpretations of earthquake safety under a new state law, according to Peter Carpenter, assistant vice-president for medical affairs.

The construction which began more than a year ago is necessary to enable the hospital to expand vitally needed support facilities, increase emergency services, and add 25 new intensive care beds. Expansion of the support facilities includes radiology, cardiology, surgical pathology, and postanesthesia recovery.

Carpenter said inflation, the energy crisis, strikes, and higher prices of materials have increased the cost of the project.

"But these factors have had relatively small impact on the project compared to the effect of the state's earthquake requirements," Carpenter said.

"Nobody at the state level has really cost-accounted the effect of the new law on hospitals," he added.

He explained that Stanford made allowances in the design of the building for the effects of the new regulations. But their slow implementation by the state resulted in many delays and revisions that could not have been anticipated.

Carpenter said at one time the University considered seriously closing down the project. "However, we could not do so, either academically or financially, because about $6 million had already been committed to the construction."

Even with the increase in budget, Carpenter said, the project has been scaled down by a decision to complete first only those parts that are most critical. A substantial portion of the interior of the building and some remodeling and equipment purchases have been deferred until funds become available.

Carpenter said fund raising for the hospital will be intensified. He also disclosed that borrowing money, or going to the state for legislative relief to recover the increased costs are some of the options under review.

The hospital's Phase I project is the first addition to the hospital since it was built 15 years ago. The need for the new building was created because needs for radiological, laboratory, and other support services have more than tripled.

STANFORD--Dr. Thomas E. Starzl, internationally known for his work in kidney and liver transplantation, has been awarded the fourth Louis and Dorothy Kovitz Visiting Professorship at Stanford University School of Medicine.

Dr. Starzl, professor and chairman of the Department of Surgery at the University of Colorado Medical Center, will deliver the Kovitz lecture on Monday, September 30, at 4:15 p.m. in Room M106 of Stanford Medical School. His subject will be "Hepatotrophic Portal Blood Factors: A Century of Controversy." The talk is open to physicians and other health professionals in the community.

The Kovitz professorship was established in 1969 by Dr. and Mrs. Louis Kovitz of Los Altos to bring outstanding lecturers to the Medical School.

Dr. Starzl performed the first human liver transplant at Colorado in July 1967.

A native of Le Mars, Iowa, he received his M.D. and Ph.D. degrees in anatomy from Northwestern University. He trained in surgery at Johns Hopkins and continued his studies at Jackson Memorial Hospital in Chicago. He joined the University of Colorado Medical Center faculty in 1962.

Dr. Starzl was named Colorado Man of the Year in 1967, and in 1970 won the Eppinger Prize in Germany for his outstanding contributions to treatment of liver disease. He has received many awards and honors, is active in several medical organizations, including membership on the General Clinical Research Centers National Advisory Committee.

An honorary member of both the Korean Medical Association and the Peruvian Academy of Surgery, he is also past officer of the International Transplantation Society and corresponding member of the Surgical Research Society of Southern Africa.

STANFORD--Epilepsy, the brain disorder which affects about two million Americans, is beginning to yield its secrets to increasingly sensitive instruments.

A major technical advance is now allowing Stanford University scientists to make important observations about epileptic discharges in experimental animals.

Reporting in a recent issue of Experimental Neurology and Brain Research, Dr. David A. Prince, Dr. Kin Futamachi, Dr. Roberto Mutani, and William J. Moody, Jr., have found significant changes in concentration of brain potassium during experimental seizures.

Potassium is an element involved in regulating excitability of nerve cells and is important in the generation of normal nerve impulses.

"Large amounts in brain potassium concentration increase excitability and may lead to epileptic seizures," explained Prince in an interview.

Until recently scientists were unable to make accurate measurements of changes in brain potassium during the actual course of epileptic activity.

But in 1971, Dr. Prince, working with Drs. H. Dieter Lux, and E. Neher of the Max Planck Institute in Munich, Germany, made the first such accurate measurements through use of highly sensitive microelectrodes which detect minute changes in potassium concentration.

Back at Stanford, Dr. Prince and his associates have continued their research under the auspices of the National Institute of Neurological Diseases and Blindness and the Epilepsy Foundation.

They have shown there is poor regulation of potassium concentration in the spaces around the nerve cells during experimental epilepsy. In fact, local potassium buildup may reach three to four times the normal level.

"This change may have important effects on the involved nerve cells and contribute to the intense discharge of nerve cells which is characteristic of epilepsy," Dr. Prince said.

The Stanford researchers are now studying scarred areas of brain similar to those which occur in humans with epilepsy. The results are expected to show whether there are disorders of potassium regulation which might be responsible for epileptic discharge.

"If such abnormalities are demonstrated," Dr. Prince added, "it may be possible to correct them with drugs or naturally occurring brain chemicals.

"The results of these experiments could have major importance to our understanding of epilepsy in man and its successful treatment."

EDITORS: Copies of Stanford M.D. available on request if not included with story.

STANFORD--Kidney patients who need dialysis on a regular basis should be trained to operate the equipment in their home, instead of traveling to a hospital or dialysis center for the treatment.

So says Dr. Belding H. Scribner, who in 1960 developed the technique of chronic dialysis (use of an artificial kidney machine which takes over the kidneys' main function of filtering out impurities from the bloodstream).

It has become cheaper for patients to remain on center dialysis and not undertake home treatment since Congress passed federal legislation in 1972 covering about 80 percent of the costs of center dialysis or kidney transplantation.

Federal regulations don't cover the costs of many aspects of home care.

"This is totally unfair," says Scribner. "Medically, psychologically, and every other way, home dialysis is better for most patients."

Scribner, a Stanford University Medical School alumnus, is at the University of Washington in Seattle and conducts research at the Northwest Kidney Center. The Center accepts all applicants, with nearly 90 percent trained for home dialysis.

His views appear in an interview in the current issue of Stanford M.D., the quarterly magazine of the Stanford Medical Alumni Association.

"If the dialysis population of the United States is 30,000, which is what we think it will be when things level off," says Scribner, "then it will cost $700 million per year to treat these patients in limited care dialysis centers. If they're treated at home, it will cost less than $300 million."

He maintains that taxpayers will have to pay over twice as much and scarce medical manpower will be used unnecessarily because of the increased use of dialysis centers.

(more)

In home dialysis the patient and one family member first complete four to eight weeks of intensive training at a dialysis center, then assume full responsibility for the operation and maintenance of the artificial kidney in their home.

They order supplies, clean and repair the machine, and respond to technical problems.

Scribner and Dr. Stanley Shaldon of London were the two pioneers of home dialysis. The concept was unheard of before their programs began in 1964.

"The idea was to make the patient as independent as possible," Scribner says. He designed the machine with special warning devices for home use, enabling the patient to sleep at home while on dialysis.

One of the major benefits of home care, in addition to the psychological and practical advantages of not being tied to a medical center, was its cost.

After initial expenditure of about $15,000 the first year for necessary supplies and equipment, maintenance costs drop to under $10,000 per year. Center dialysis, on the other hand, costs roughly $15,000 per year, according to Scribner.

Scribner devised the first arteriovenous shunt for a Seattle patient in 1960.

He inserted plastic tubes in an artery and a vein of the patient's arm, and kept the access open by hooking the tubes together, creating a shunt. During dialysis, the shunt would be pulled out and replaced by the lines to the artificial kidney.

Overnight, with permanent access to the bloodstream available, lives that once were considered lost could be saved by repeated dialysis.

The longest survivor, one of Scribner's first patients in Seattle, has lived more than 14 years.

Before his work, dialysis had been an operating room procedure performed to preserve the life of patients with temporary kidney failure, to keep them alive until their own kidneys returned to normal. Patients whose kidneys did not recover, soon died.

In addition to promoting home dialysis, Scribner strongly feels that a national registry of all patients with chronic kidney failure is necessary. Such a registry would help ensure that patients seeking a transplant would be tissue-matched with every available donated kidney.

At present, there are two separate registries: one for dialysis patients and one for transplant patients, making it impossible to follow the course of the patient when he shifts from one form of treatment to the other.

Scribner is also currently concerned with new ways to prevent coronary artery disease, the number one problem for long-term patients. It is believed caused by a combination of factors, including abnormal lipid metabolism on dialysis.

STANFORD--United Stanford Employees has filed a petition with the National Labor Relations Board seeking to represent more than 1,000 employees at the Stanford University Hospital.

Filed last week, the petition proposes a bargaining unit including "all patient care, technical, service and support personnel, including pharmacists, licensed vocational nurses, and nursing clerks..(and) excluding all registered nurses, office clerical employees, guards, and supervisors."

Provisions of the Taft-Hartley Act were amended earlier this year to cover nonprofit hospitals.

The USE petition lists the California Licensed Vocational Nurses Association as an interested union. This group has negotiated but not yet executed a new contract covering licensed vocational nurses at the Hospital. Under NLRB rules, a union may be selected to represent employees previously represented by another union if a written contract between that union and the hospital is not in effect.

John Meakins is the NLRB agent for the petition. The board's practice calls for an investigation to determine if hearings are necessary on the petition.

USE is local 680 of the Service Employees International Union, AFL-CIO.

###

STANFORD--Approximately 30 per cent of the in-coming class of Stanford medical students will be women, an increase of about four per cent from last year.

Classes for an anticipated 86 first-year students begin September 25.

John P. Steward, associate dean of student affairs at Stanford School of Medicine, sees the steady rise of new women medical students as "a very good thing." He believes the pattern will continue and says a future class of med students equally divided between men and women is not "out of the question."

At Stanford there were 4,553 applicants for this year's class, an increase of 420 from 1973. Women students comprised 12 per cent of the first-year medical students at Stanford in 1966 and fell to three per cent in 1969 But since 1970 the number of women students has steadily risen from 10 per cent to 26 per cent last year.

Nationally, 21 per cent of first-year medical students are expected to be women this year (average), according to the American Medical Association's Council on Medical Education. The national average five years ago was 9.1 per cent.

(ADVANCE) FOR RELEASE IN P.M. PAPERS THURSDAY, SEPTEMBER 12, 1974.

STANFORD--Some people can't digest table sugar, just as some can't digest the lactose in milk, says a Stanford University scientist.

This is why they experience feelings of distention and suffer diarrhea when they eat sugar.

The problem seems to be a hereditary deficiency in the enzyme that breaks down sugar, explains Dr. Gary M. Gray, associate professor and head of the division of gastroenterology at the Stanford University School of Medicine.

The enzyme normally allows the sugar to be split in the intestine so that the smaller products such as glucose can be assimilated into the body.

Dr. Gray made his remarks in a paper scheduled for presentation Thursday (September 12) at the meeting of the American Chemical Society in Atlantic City.

Contrary to earlier thought, Dr. Gray said, most digestion takes place not by the action of intestinal "juices," but rather by the action of enzymes imbedded in the surface of cells lining the small intestine.

Scientists at Stanford have recently isolated and characterized some of the enzymes active on this intestinal surface. One of these is sucrase, the enzyme that breaks down sugar.

If the enzyme is not present, sugar from the diet remains in the intestine and by osmotic action draws water out of the tissues into the intestine, creating a bloated feeling and resulting in a watery diarrhea.

Stanford researchers Drs. Edward Silverblatt and Gray have discovered that in normal people the sucrase enzyme is manufactured by immature intestinal cells as a protein that initially lacks the ability to split sugar. As the intestinal cells mature within only a few hours, the protein undergoes a change that enables it to digest the sugar.

Little is known about the factors that control either the manufacture of the immature protein or its conversion to the mature active sucrase.

The studies have shown that patients who cannot digest sugar still possess the immature sucrases. Gray suspects some genetic deficiency results in failure of the conversion of the inactive protein to the active form of sucrase.

Segments of some populations seem to be deficient in producing the enzyme, perhaps due to a traditional lack of sugar in their diet, says Gray. He cites particularly the Eskimos as such a group.

Tolerance of some people to milk has been linked to hereditary adaptations, according to earlier work by Dr. Norman Kretchmer, former Stanford pediatrician. It has been proposed that a genetic mutation enabling man to digest milk (lactose) probably occurred at least 10,000 years ago when some groups began to milk animals.

The inability to digest lactose has been found to be world-wide and not uncommon. The inability to digest sucrose however, is much more rare.

The research on sugar digestion is supported in part by grants from the National Institutes of Health.

FOR FURTHER INFORMATION CONTACT: Bob Tapia (415) 497-6911

STANFORD--Site preparation work began this week for Stanford University Medical School's Sherman Fairchild Center for the Neurosciences, which will include a main building and adjacent auditorium.

This is one of four construction projects currently underway around the medical center. The others include a new hospital wing, Renal Care Unit Building and Governor's Lane Complex.

Due to the increasing inflation factor, the multi-million dollar expansion program at Stanford University Medical Center is expected to be scaled down somewhat in final design and equipment costs.

A number of sub-contractors are involved in construction of the Fairchild Center with the Turner Construction Co. of San Francisco serving as construction manager.

The projects include:

--Sherman Fairchild Center for the Neurosciences, which will be situated south of the Medical Center. This $9.75 million facility is tentatively scheduled to be completed by August, 1976. The neurosciences building will be three stories and a full basement, according to plans, and will house the departments of anatomy-physiology and neurobiology (a new department). The auditorium will provide seating for 400 persons, a lobby and display area and enclosed facilities for a projection room, preparation rooms, storage and administrative space. Large lecture classes and meetings can be accommodated in this facility (the limit is 145 persons in the existing lecture amphitheatre). The Fairchild building was designed by the architectural firm of Stone, Marraccini and Patterson of San Francisco. The Fairchild Foundation of Greenwich, Connecticut has pledged $8.25 million for construction of the center, which is named after the founder of Fairchild Camera and Instrument Corp. and Fairchild Industries.

--Hospital wing, which will add vitally needed support facilities, including 25 intensive care beds, increased emergency services, radiology, cardiology, surgical pathology and post-anesthesia recovery. Initially, Stanford University Trustees approved a budget of $9.5 million for this project, but recently they revised that figure upward to $12.6 million due to increased construction, equipment costs and code

- more -

requirements. This facility is tentatively scheduled to be completed and in operation by December, 1975, even though a substantial portion of the interior of the building and some remodeling and equipment purchases have been deferred until more funds become available.

--Governor's Lane Complex, west of the medical center, which will initially contain a research building for the lymphoma virology program of the Department of Radiology. The two-story structure will contain approximately 10,000 square feet of space and is scheduled for completion in June, 1975. Much of the project costs of $1,155,000 will be borne by the National Cancer Institute. Dr. Henry S. Kaplan, professor of radiology and a cancer research pioneer, will direct the program and his work will deal with several aspects of the biology of human malignant cancers, including Hodgkin's disease. In the new laboratory methods will be devised for the study of human cancer cells, with emphasis on the possible role of viruses in the cause of malignant disease.

--Renal Care Unit, which is located southwest of the Psychiatry Building, is scheduled to be completed in early November. This temporary structure, which costs approximately $185,000, is being designed to handle kidney dialysis for seven patients at a time.

Peter F. Carpenter, assistant vice president for medical affairs, noted that recent costs hikes involving construction of the new hospital wing were caused by design changes required under state laws for earthquake safety. He said that Stanford has made allowances in designing the new wing to conform with new state regulations. However, slow implementation of the regulations by the state has resulted in many delays and revisions that were not anticipated, he said.

Even with the budget increase, the project has been scaled down by a decision to complete first only those parts that are most critical, he added. Furthermore, a substantial portion of the interior of the building and some remodeling and equipment purchases have been deferred until funds become available.

Carpenter said fund raising for the hospital will be intensified and he noted that several options are under review to recover the increased costs, including the borrowing of money.

The new hospital wing is the first addition to the facility since it was built 15 years ago. The need for the new building was created when radiological, laboratory and other support services more than tripled.

FOR IMMEDIATE RELEASE
STANFORD –

Itamar Barnea might appear to be just another student at the University of Jerusalem in Israel, but it is doubtful if many other students can match his experiences.

Barnea, 24, an ace pilot in the Israeli Air Force, recently returned to his homeland after undergoing intricate corrective surgery at Stanford University Hospital to repair internal complications from wounds he suffered in the last Mideast war.

He spent eight months in a POW compound in Syria after his Phantom jet was shot down Oct. 21, 1973, while he was on his 60th mission in 12 days. His was officially listed as the last plane to be shot down in the war. He escaped from the plane and while plummeting in his parachute he was wounded by rifle fire from soldiers on the ground. One bullet went through the right side of his chest in the front and exited through the back.

However he survived and was treated by a Russian-trained surgeon who subsequently removed his right lung. Following repatriation, Barnea was examined at Hadassah Hospital in Jerusalem where physicians decided to call in Dr. Karlman Wasserman, former assistant professor of medicine at Stanford, who was in Israel at the time as a visiting professor. Wasserman, who is now a professor of medicine at UCLA, is a specialist in chest disease.

He made arrangements with the Israeli government to have Barnea flown to the U.S. and asked Dr. Robert W. Jamplis to conduct the operation. Jamplis, who is chief of thoracic surgery at Palo Alto Medical Clinic and clinical professor of surgery at Stanford University Medical Center, had worked previously with Wasserman at Stanford.

"Itamar had several problems," Jamplis explained, "shortness of breath and a bad cough. We thought his breathlessness was due to an overexpansion of the left lung into the empty right cavity, and his coughing caused by turbulence of air in the windpipe. He also had a wheeze, since his left lung was pulled so far into his right chest that it shut off the air to the left part of the left lung."

Jamplis feels it is remarkable that the young man has recovered from the ordeal, since he probably received little postoperative care during his many months as a POW. "His heart had been pulled into the right chest so far that it was right under the right ribs," Jamplis noted. "We had to devise an operation that would push the heart and windpipe back into the mid-line of the chest and have it hold there."

(more) cr 10/28/74

Jamplis said silastic implants had been considered at one point in order to keep vital organs in the chest from shifting back. (Silastic implants are silicone-based materials sometimes used as supportive replacements for organs removed by surgery.)

He consulted with Dr. Harvey Lash, head of plastic and reconstructive surgery at Palo Alto Medical Clinic, before deciding that implants would not be necessary. "We didn't really know what we would do until we opened the chest," Jamplis recalled, "but we decided to have everything ready."

Although Barnea would have survived without surgery, he most likely would have had "chronic infection" in part of the chest cavity, according to Jamplis. "Now that he's home he won't need more treatment. I would hope that he would be able to live a normal life."

Although reluctant to talk about his military experiences, the soft-spoken Barnea remains bitter over medical treatment he received while in captivity. "The operation caused me a lot of troubles. But I was lucky because I met some doctors from the U.S. who helped me to get my second operation."

Barnea says it was just a lucky "accident" for him that Wasserman was in Israel at the time and that the physician agreed to make arrangements for him to fly to the U.S. The plans were coordinated through the pilot's father-in-law and personal physician, Dr. Zvi Eyal, professor of surgery at Hadassah, who accompanied Barnea to the U.S.

The young ex-prisoner of war who lives with his wife, Taly, and six-month-old daughter, Lilach, is optimistic he will be able to return to his former lifestyle without too much discomfort. As a student he plans to take some biology and psychology courses and eventually return to the military, possibly in a teaching position.

It is unlikely he will return to his former job as a military pilot. His wife, meanwhile, has already attended the University of Jerusalem for two years and plans to go into social work.

Following his release from Stanford Hospital, Barnea underwent some postoperative tests in Los Angeles by Wasserman and then flew to Tel Aviv via New York.

"It will take time [to recover]," Barnea sighed. "I felt like an old man before, with shortness of breath and all. But I feel better already."

STANFORD — Patients treated for obesity often suffer from emotional troubles.

These troubles differ in intensity and duration and are related to the type of patient and to the place and kind of treatment.

Persons who were obese as children are much more predisposed to having emotional difficulties as a result of dieting than patients who become obese in adult life.

Short-term fasting in a hospital environment causes less stress to patients than programs in which there is severe caloric restriction.

These conclusions are reached in an article by Dr. Albert J. Stunkard, professor and chairman of the Department of Psychiatry and Behavioral Sciences at Stanford University.

Stunkard in collaboration with Dr. John Rush, a University of Pennsylvania psychiatrist, reviewed their own as well as other studies of long-term and short-term fasting during the past 22 years.

"There is striking unanimity of findings about the benign effects of short-term fasting," they reported in the October issue of *The Annals of Internal Medicine*.

There are three major treatments for patients hospitalized for obesity: short-term fasts lasting no longer than two weeks, low-calorie diets, and long-term fasts which may last from two weeks to 40 days.

For fasting that lasted from 10 to 40 days there was a dramatic rise in emotional disturbance, Stunkard reported. In one study, patients "showed definite mood fluctuations of marked degree," increased aggression, and even "near psychotic episodes." In another study there were two suicide attempts.

Low-calorie diets caused the same degree of emotional upsets as long-term fasting, the psychiatrist said.

The psychiatrists noted that severe emotional disturbances nearly always appeared after patients had either lost 15 to 20 pounds of weight or had been in the hospital more than 10 days, or both.

"These may be the critical values," Stunkard said. "They suggest that the disturbances may, in part at least, be precipitated by metabolic changes, which doubtless occur in long-term fasting."

Stunkard said persons who became overweight in childhood were more difficult to treat and had more emotional difficulties than patients whose obesity began in adult life.

The most dramatic evidence for this special vulnerability was found by researchers at Rockefeller University in 1968. "It was the most distinctive factor in vulnerability yet identified," said Stunkard.

The psychiatrists hope that making these facts better known would aid the profession in making more informed decisions about obesity treatment.

"It might help both doctors and patients to realize just how difficult weight reduction can be and to lessen unrealistic expectations of treatment," Dr. Stunkard commented.

"Such help might even make physicians more tolerant and patients less guilty."

STANFORD--A new blood test that acts as "an early warning system" for detecting graft rejection in heart transplant patients has been developed by surgeons at Stanford University School of Medicine.

Five patients were studied with the new test called the modified reactive leukocyte blastogenesis (MRLB) assay. The patients were monitored for 45 to 75 days after they had received heart transplants at Stanford University Hospital. There were 18 documented rejection episodes in these patients.

Test results were compared with two other methods now used to detect rejection. These are the electrocardiogram and heart tissue biopsies.

The MRLB test predicted rejection almost five days earlier than the other methods, and continued to be as sensitive in predicting subsequent episodes, the researchers reported.

The scientists are Randall E. Morris, Dr. Eugene Dong, Jr., Charlene M. Struthers, Dr. Randall Griepp, Dr. Edward B. Stinson, Dr. Margaret Billingham, and Dr. Norman E. Shumway. Morris is a fourth-year medical student and Miss Struthers is a student in human biology. Their findings were presented Monday (Oct. 21) at the meeting of the American College of Surgeons in Miami Beach.

"This test should be applicable in diagnosing rejection of transplanted organs other than the heart," their report said. "However, more experience with the test would be needed before determining the ultimate benefit to patients."

The surgeons believe that detecting rejection in its earliest stages would require less medication to reverse it. This would lessen risk to patients.

Drugs now used to suppress the immune reaction in these patients act as a two-edged sword, the surgeons said. They reverse rejection, but they also predispose patients to infections and malignancies.

- more -

"The undesirable effects of these drugs could be avoided through more judicious administration," they commented.

The MLRB test works this way:

Tissue rejection in the body is a two-stage process. In the first stage immune cells begin to multiply. In the second stage the immune cells invade the graft and destroy it.

The MRLB test detects immune cell division as soon as it gets under way. It does so by monitoring the synthesis of DNA (deoxyribonucleic acid), the hereditary material of cells that is essential for division.

To monitor DNA synthesis, a blood sample is obtained as often as needed from the patient and incubated in a test tube containing nutrients essential for the growth of blood cells outside the body. The incubation solution contains a radioactively labeled DNA building block (tritiated thymidine). Actively dividing cells incorporate the thymidine into their newly synthesized DNA, providing a clue that the immune system is being mobilized.

This signals the time to begin antirejection treatment.

Stanford Medical Center is one of the few institutions in the United States where heart transplants are being performed. Of the 77 patients who received new hearts at Stanford, 26 survive.

According to a recent report, survival for all transplant patients operated on at Stanford was 44 percent surviving at one year, 39 percent at two years, 24 percent at three years, and 20 percent at four and five years--for an overall figure of 33 percent. In the past year the one-year figure has been 50 percent.

FOR IMMEDIATE RELEASE
STANFORD –

When he entered Stanford Hospital last week, Henry Gearing was virtually blind; he walked with a cane to avoid bumping into objects.

A few days later, thanks to a relatively new and delicate surgical procedure, he walked out the door unaided, enjoying his first views of the world in six months.

Gearing has diabetes, which often causes eye complications. His problem began in the retina, the eye tissue that acts like film in a camera to pick up images and transmit them to the brain.

The condition, called diabetic retinopathy, is the most common cause of new blindness in U.S. adults today, according to Dr. A. Ralph Rosenthal, head of the division of ophthalmology at Stanford Medical School.

New blood vessels form in the retina, Rosenthal explained. These vessels are fragile and often burst, spilling blood into the jelly-like vitreous cavity that surrounds the retina. The blood clots in the vitreous prevent light from reaching the retina.

Both of Gearing's eyes had hemorrhaged periodically for two years. Finally, six months ago, his vision was totally blocked.

"It was like looking through milk," he said. "Nothing came through."

An operation to remove the dense clot could restore Gearing's vision. The technique, called vitrectomy, has only been performed regularly for about a year. It requires microscopic precision and special lighting, and newly designed equipment not yet available in many hospitals.

When Gearing and his wife, residents of Cleveland, Ohio, were visiting a son who lives in the Bay Area, they discovered that Stanford was one of four hospitals where vitrectomies were done on the West Coast.

Gearing's operation was performed by Dr. Robert Jack, clinical instructor of ophthalmology at Stanford School of Medicine and a staff ophthalmologist of the Palo Alto Medical Clinic, who studied the procedure in Miami where it was pioneered two years ago.

Jack inserted a mechanized probe with a rotary cutting edge into the vitreous cavity of Gearing's left eye. The blade "chopped up" the clotted vitreous blood, which was then sucked up a hollow tube of the probe. The extracted clot was replaced by a clear saline solution, administered through another tube of the probe.

Twenty-four hours after the operation, Jack removed the bandage from Gearing's eye. "It was beautiful," said Gearing. "I could see the faces and features of everyone around me."

"Gearing's case is particularly dramatic," pointed out Jack, "because both eyes were affected. He could see nothing the day before surgery, and saw so well the morning after the operation. It is not unusual for several weeks to elapse before the eye clears after vitrectomy surgery."

Although it's too early for any long-term prediction on the success of the operation, the results so far have been very promising, said Jack. He doesn't foresee any more hemorrhages for Gearing. As additional insurance against future bleeding, Gearing will undergo periodic laser treatments.

In another month he returns to Stanford for a repeat performance on the right eye. The retired employee of U.S. Steel looks forward to resuming his fishing and traveling with two good eyes. But nothing can surpass the thrill of this first operation.

"I can't get over how wonderful it is to see again. Just being able to tell time from the clock is a precious experience," Gearing said eagerly, turning his head to take in everything around him. –30– 10/8/74 cr

Editors: A press conference to announce plans for incorporation of a comprehensive cancer center program for northern California and northwestern Nevada has been scheduled by the American Cancer Society at 9:45 a.m. Thursday, October 3, 1974 in the Lassen Room, San Francisco Hilton. The story is issued simultaneously with a similar release distributed by the ACS.

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos (415) 497-6911
FOR RELEASE IN P.M. PAPERS THURSDAY, OCT. 3, 1974. Charles Dahle, ACS (415) 777-1800

SAN FRANCISCO--Plans for a major comprehensive cancer center program which will be based in the San Francisco Bay Area and serve all of northern California and northwestern Nevada were made public here Thursday (Oct. 3).

The plans call for creation of a new organization which will be known as the Northern California Cancer Program. Papers of incorporation of the coordinating body will be signed within the next few weeks.

The program will include several organizations already involved in cancer research and treatment activities, among them--the University of California School of Medicine, San Francisco, the American Cancer Society, and the Stanford University School of Medicine.

The new program was described at a press conference in the San Francisco Hilton by Dean Julius R. Krevans of the University of California School of Medicine in San Francisco; Robert F. Murphy, executive vice president of the American Cancer Society; and Dr. Saul A. Rosenberg of the Stanford University School of Medicine.

When in operation, it is expected that the California Cancer Program will be financed in large part--but not entirely--by the National Cancer Institute. Sixteen existing centers have current budgets ranging from $700,000 to $12.6 million or an average of about $3 million per year. No major financial commitments have been made except for seed money which will be provided by some of the participating institutions to get the program going.

However, once it is incorporated, the Northern California Cancer Program will apply to the National Cancer Institute for increasing working funds, it was disclosed.

The 16 comprehensive cancer centers already in operation elsewhere in the nation, include one in Los Angeles under joint sponsorship of the University of Southern California and Los Angeles County Hospital, and another in Seattle under joint sponsorship of the University of Washington, the Fred Hutchinson Cancer Research Center and the Children's Orthopedic Hospital and Medical Center.

The Northern California Cancer program will have no buildings of its own, but will work through existing facilities and institutions including community hospitals. Lay programs of the American Cancer Society also will be coordinated with the plan.

- more -

22--Cancer Center

The planning group foresees, in addition to the coordination of basic science and clinical investigation, the expansion of training programs for various categories of medical and hospital personnel, the establishment of new and enlarged cancer detection and resource clinics, consultation services and radiotherapy networks; the development of uniform procedures in pathology and epidemiology, the expansion of public education programs, and a continuing evaluation of results.

The local planning committee is chaired by Dr. Rosenberg, professor and head of the division of oncology at Stanford. Among its most active members have been representatives from the University of California at Berkeley and San Francisco, Stanford University, the San Francisco Regional Tumor Institute, the West Coast Cancer Foundation, the California Medical Association, The California State Health Department, the Northern California Cancer Council, Inc., and a number of leading community hospitals in the area.

Three members of the planning group serve as representatives of the lay community. They are attorney B. J. Feigenbaum, banker Edward J. Schneider, and American Cancer Society executive Murphy.

Dr. G. Denman Hammond, director of the center at U.S.C., Dr. John Hartmann, associate director of the center in Seattle, and Dr. Jesse Steinfeld, former U.S. surgeon general, have been serving as advisers to the local group along with officials from the headquarters of the National Cancer Institute.

The San Francisco Bay Area has for nearly three decades been recognized as one of the nation's foremost centers of cancer research. It has been strong in basic research, surgery and chemotherapy, and has been a pioneer in the development of high voltage radiation and nuclear medicine. It has grown as a center of cancer research because of the size and spread of the universities and hospitals clustered here. In this respect it is unlike most other major areas, where single institutions have tended to become dominant in the field. It is expected that the Northern California Cancer Program will combine all of the present anti-cancer activities into a coordinated effort involving not only research but public and professional education and some aspects of service to cancer patients.

According to the ACS, current funding of scientific and lay programs in cancer research and control in northern California totals approximately $15 million annually from the National Cancer Institute and the American Cancer Society alone. Of this amount, about $9.7 million comes from NCI, and $5.25 million from ACS.

STANFORD--Through the assistance of a sophisticated brain-scanning device, Stanford doctors hope to better understand the nature of brain disease.

The Department of Radiology at Stanford Medical Center recently placed its new EMI Scanner into operation and patients with suspected brain disorders are being examined by the machine on a daily basis.

The device, which was developed by a British firm, utilizes an X-ray beam, computer analysis and Polaroid film. It is able to detect benign and malignant brain tumors, blood clots, brain injuries, brain defects resulting from strokes and certain birth defects.

The machine is considered "revolutionary" in some medical circles in the diagnosis of brain disease, but Dr. William Scott, acting assistant professor of radiology at Stanford, believes the device will also aid scientists through extensive research into gaining fundamental information about various brain diseases.

The scanner, which Scott estimates costs approximately $380,000, was actually purchased by Stanford late last year. However, there was a nine to 10 month waiting period for delivery so the unit did not become operational until last summer. In the near future the machine will be installed with a modification developed by the manufacturer which gives the computerized X-ray readings a finer detail. The modification costs approximately $12,000.

Scott is convinced the scanner can be used as the takeoff point for research into areas involving actual and potential brain disease.

He believes animals can be used in a number of experimental research projects. He noted that spinal flow and any brain disorders such as tumors, could be studied by the scan. The animals used in an EMI Scanner study would be temporarily sedated because they must be held still during the scanning process. Humans must also be still and the scan can usually be completed in 20 to 25 minutes.

(more)

Although Scott considers the scanner a major breakthrough in the study and detection of brain disorders he stressed that it does not totally replace old tests previously used. "We expect to shorten the hospitalization in some patients," he said, "and to other patients the scan will act as a supplement to other tests."

Those "other" tests are pneumoencephalograms and angiograms. In pneumoencephalograms the brain and head chamber are outlined with air before X-rays are taken, while with angiograms substances are injected into arteries of the patient's brain before X-rays are made. Both of these procedures entail some risk, are more time consuming and cause some discomfort to the patient, Scott says.

To be scanned, the patient lies flat on his back while an X-ray tube and X-ray detectors move across his head. Information from the detectors is then analyzed by computer following a visual display of the results on an oscilloscope. This information represents a cross-section, or a horizontal "slice" of the brain. By comparing slices doctors can determine the depth of a tumor and by comparing the various shades of gray they can distinguish between tumors and other disorders, such as damage from strokes.

This process represents a major advance since the brain is inaccessible by the more standardized X-ray devices because of the density of skull bone encasing. More important to the patient, there is less X-ray exposure with the EMI Scanner than with more conventional X-ray scans, Scott said.

Although Stanford operates an EMI Scanner so does the Palo Alto Medical Clinic, which actually received its machine a month before the university did. According to Scott, Stanford and the clinic plan to work together on joint clinical research utilizing both scanners in the near future.

He noted, furthermore, that Stanford will scan patients for smaller hospitals that cannot afford their own EMI Scanners. In all, he estimates about one-half dozen scanners are either in operation or soon will be in the greater San Francisco Bay Area.

What is the life span of the EMI Scanner? Will better scanners soon replace it?

"More sophisticated, similar equipment to further improve resolution (detail) and speed of study will likely make the present scanner model outdated within three to five years," Scott predicted. "However, the present equipment is astonishingly useful, providing information essential to the care of large numbers of neurologic patients."

STANFORD--A preliminary hearing is scheduled Tuesday, November 26 in U.S. District Court in San Francisco on a class action suit filed by two Stanford resident physicians who want a "loyalty questionnaire" required by the Veterans Administration invalidated.

The suit, filed in behalf of Drs. Peter Rudd and Steven Oboler, seeks to eliminate the questionnaire which asks potential employees at VA facilities about their affiliation with political organizations, including the Communist party.

An earlier suit, in which Rudd was one of the plaintiffs, was upheld last year by the U.S. Ninth Circuit Court of Appeals thereby throwing out a similar questionnaire. The court ruled then that such a questionnaire did not have to be filled out by physicians working at VA hospitals because it infringed upon individual rights granted by the First Amendment. The government did not appeal that ruling to the Supreme Court.

Approximately 10 years ago Dr. June Fisher refused to answer a VA questionnaire during her residency at Stanford and subsequently worked without pay at the VA Hospital in Palo Alto. Several other physicians at the facility followed suit and either worked without pay or forfeited their opportunity to work at the VA.

The original suit was initiated by Drs. Rudd, Howard Waitzkin and Peter Cummings, all of whom were interns at the time but did not work together. All three refused to answer the questionnaire. They were on the house staff at Stanford Hospital when the first suit was filed and were scheduled to serve clinical rotation at Palo Alto VA Hospital.

Stanford resident doctors generally serve rotations at affiliated hospitals, of which VA Hospital is one.

Shortly after the revised form, which is called "G.C. 51," was distributed to some VA hospitals around the country, Oboler was requested to sign the form. He refused and the new class suit was initiated.

"Political affiliations, like religion or race, should not be included among the conditions for employment," Rudd commented. "We are anxious for people to know about this case."

A spokesman at the VA's regional office in San Francisco said the VA would not comment on the suit while it is in litigation.

The physicians have spent approximately $6,000 for legal costs and have hired attorney Marshall Kraus of San Rafael to represent them in the latest suit. The preliminary hearing November 26 at 2 p.m. will be before Judge Oliver Carter.

FOR IMMEDIATE RELEASE
STANFORD –

Stanford University's Lipid Research Clinic has received a contract for $738,590 from the National Heart and Lung Institute to support its on-going study of the effectiveness of reducing blood cholesterol levels in the prevention of heart disease.

A recruiting drive continues in the Bay Area to enlist persons with high cholesterol levels for the five to seven year study, according to Dr. Michael Stern, director of the Stanford program.

The Stanford effort is part of a research program being conducted at 11 clinical centers nationwide and one in Canada, with support from the National Institutes of Health.

Researchers hope to produce conclusive data concerning whether or not cholesterol lowering will prevent the development of heart disease.

Doctors expect to screen thousands of people in the Bay Area, since only an expected one percent of those initially screened will be found suitable for the program.

Nationally, approximately 4,000 male volunteers, aged 35 to 59, will participate. Besides other requirements, candidates must have cholesterol counts of at least 275 milligrams per milliliter of blood or above, but not have symptoms of heart disease.

One group of volunteers accepted into the program will be placed on a special low cholesterol diet. The other group, in addition to the diet, will receive doses of a drug intended to reduce their cholesterol level even further. Those not receiving the drug will receive a placebo.

All participants will receive frequent regular physical examinations to monitor their health.

Community physicians, area blood banks, clinical laboratories, and other medical organizations are assisting in recruiting efforts for the study. Persons interested in participating may contact the Stanford Heart Disease Prevention Program at 730 Welch Road, Palo Alto, CA 94304. Telephone is 329-1300.

EDITORS: Release date for this story has been set to coincide with presentation of the research report at the American Heart Association meeting in Dallas.

ADVANCE FOR RELEASE AFTER 6 P.M., WEDNESDAY, NOVEMBER 20, 1974.

STANFORD — Middle-aged men may reduce their chances of developing heart disease if they engage in vigorous physical activity, like long distance running, says a group of Stanford researchers.

Scientists discovered that male runners they studied, aged 35 to 59, had blood fat distribution more like younger women than like less active middle-aged men. Young women comprise a group that is rarely afflicted by heart disease.

Dr. Peter D. Wood, adjunct professor of medicine at Stanford University Medical Center, and Herbert Klein, Steven Lewis, and Dr. William Haskell presented their findings at the annual scientific session of the American Heart Association meeting in Dallas on Wednesday, Nov. 20.

Their work represents solid evidence to support contentions that strenuous physical activity by older men is beneficial with respect to avoiding heart disease. They cautioned, however, that no such vigorous exercise program should be launched without sufficient preconditioning and advice from a physician.

The runners were a Northern California group of 41 male long-distance runners who averaged at least 15 miles of running each week during the preceding year. Many had begun their habit within the last few years and were not lifelong athletes. They were all in excellent physical condition, as measured by treadmill testing.

Compared with this group was a larger group of randomly selected middle-aged men, more representative of the entire male population, according to Wood, and generally rather sedentary.

Researchers found cholesterol levels modestly lower in the runners. Most significantly, they found changes in the distribution of cholesterol in the blood lipoproteins which carry the fats through the body circulation. Cholesterol in low density lipoproteins, generally considered an important risk factor for heart disease, was only 125 in runners, but 139 in the control group. Plasma triglyceride levels were very much lower in the runners than in the control group (70 versus 146), confirming previous reports.

"It is interesting to note that these older male runners show a pattern of cholesterol and triglyceride distribution that is more like that of younger women than that of males of the same age who are sedentary," says Wood.

The continued presence of excess fats in blood plasma is thought to increase the chances that these fats will accumulate in the artery walls. If this occurs in a coronary artery, reduced or obstructed blood flow could result in heart attack.

The recent research indicates that vigorous exercise may help to slow down this process of fat accumulation.

None of the runners smoked cigarettes, and most were close to ideal weight. However, says Dr. Wood, the data suggest that it was the exercising and not these other factors that was primarily responsible for the distribution of fats in the runners.

The researchers conclude: "Vigorous activity in older men is associated with a pattern of blood lipids considered by most authorities to be conducive to heart health, and that such activity is to be commended, at least from this point of view, in fit individuals."

Wood himself is considered one of the finest senior distance runners in the country, and has often stressed the positive effects exercise can have in respect to heart disease.

He was named most outstanding senior runner in Northern California in 1970 by a ballot of the Amateur Athletic Union runners. The 45-year-old lipid chemist from London runs up to 100 miles a week when training for marathon races.

STANFORD--Dr. Albert J. Stunkard, professor and chairman of the Department of Psychiatry at the Stanford University School of Medicine, has asked to be relieved of his administrative responsibilities.

In a letter to Dr. Clayton Rich, vice-president for medical affairs and dean of the medical school, Stunkard cited personal reasons for his decision.

He plans to continue his Stanford association as professor of psychiatry and director of the newly established eating disorders clinic.

Dean Rich said he has the highest regard for Stunkard. "I look forward to his continuing contributions to the psychiatric teaching and clinical programs."

Rich has appointed Dr. Thomas A. Gonda, professor of psychiatry, as acting chairman of the department. The appointment is effective immediately. He has also appointed a committee to advise on the selection of a new chairman. The committee is headed by Dr. Philip C. Larson, Jr., professor and chairman of the Department of Anesthesia.

Gonda, 53, is currently medical director of the Stanford Hospital and an associate dean for clinical affairs.

Stunkard became psychiatry chairman at Stanford in 1973. Prior to that he headed the department of psychiatry at the University of Pennsylvania School of Medicine.

STANFORD--Dr. Erich Lindemann, visiting professor of psychiatry at Stanford University School of Medicine and one of the world's most distinguished psychiatrists, died Saturday, November 16, at his home in Palo Alto, California, after a lengthy illness.

Lindemann, 74, was also professor emeritus of psychiatry at Harvard Medical School and former chief of psychiatry at the Massachusetts General Hospital in Boston. He had been a clinical teacher and consultant in mental health at Stanford since he retired in 1965 from 30 years of active service at Harvard.

As an experimental psychiatrist and pyschologist, Lindemann pioneered studies on how people react to loss and grief, and developed an original approach to the origin of mental disease in an American community.

His interest in changes in the social structure which affect an individual's mental well-being began in 1942 when he was called upon to aid victims of the Coconut Grove fire in Boston where hundreds of persons were killed and injured.

Six years later he was responsible for establishing the first community health center in Wellesley, Massachusetts, to study community conditions that can lead to mental breakdown.

Lindemann also headed the West-End project, in which some 2,600 families in the West-End area of Boston were forced to relocate in 1957. He and his colleagues conducted a systematic appraisal of the social and psychological stresses involved in relocation.

A native of Witten, Germany, Lindemann received a Ph. D. in 1922 and an M.D. in 1926 from the University of Giessen. He came to the United States in 1927 and served on the faculty of the University of Iowa for the next eight years. Since 1935 he was associated with Harvard and the Massachusetts General Hospital, and became professor and chief psychiatrist in 1954.

Survivors include his wife, Elizabeth B. of Palo Alto, a daughter, Brenda of San Raphael, a son, Jeffrey of San Francisco, and two sisters and a brother of Germany. Remains will be sent to Plainfield, Vermont.

EDITORS: Release date for this story has been set to coincide with presentation of the research report at the American Heart Association meeting in Dallas.

ADVANCE FOR RELEASE IN AM PAPERS, WEDNESDAY, NOVEMBER 20, 1974.

STANFORD--Studies in three California communities suggest that mass media campaigns can persuade people to change habits believed to increase risk to heart attacks, and can result in significant changes, such as lower blood pressure and cholesterol levels.

The results are from the first phase of a three-year Stanford program launched in 1972 using mass media campaigns in an attempt to persuade people to change high risk habits such as cigarette smoking, diet, and lack of exercise.

Results were presented at the scientific sessions of the American Heart Association in Dallas on Wednesday (November 20) by Dr. William Haskell and his colleagues of the Stanford Heart Disease Prevention Program.

In the community of Gilroy, a random sample of approximately 500 men and women aged 35 through 59 were surveyed before and after a Spanish and English media campaign by radio and television, newspapers, billboards, and mail. The campaign focused on smoking, physical activity and exercise, weight, and consumption of cholesterol, saturated fats, sugar, salt and alcohol. Before and after the campaign all participants had physical examinations and completed written questionnaires.

In Watsonville, the same campaign was carried out. In addition, a smaller number of persons were given personalized, intensive information by teams of physicians, dieticians and other health personnel. These people had been judged to be high-risk for heart disease during initial examinations.

In Tracy, a random sample of persons were surveyed at the beginning of the study, and then again a year later. There was no media campaign to educate them about heart disease.

Results for the first year show a reduction of 2.5 percent in the cholesterol level of persons tested in Watsonville, compared with increases in the cholesterol level of Gilroy participants of 0.6 percent, and 3.1 percent in Tracy.

Levels of triglyceride (a form of dietary fat in the blood) were reduced by 4.9 percent in Watsonville, but increased 5.5 percent in Gilroy and 16 percent in Tracy.

Blood pressure of participants in Watsonville was reduced by 1.6 percent, and by 2.7 percent in Gilroy, compared with an increase of 4 percent for those surveyed in Tracy, where there was no media campaign.

- more -

Respondents in Watsonville reported that they smoked 31 percent less cigarettes after the one-year campaign. Gilroy subjects reported a 9 percent reduction in smoking, and Tracy reported a 4 percent reduction. Weight reductions of about one percent were reported in all three communities.

Besides the physiological changes, results also confirm the researchers' hunch that changes in knowledge and behavior are possible. For example, more than 15 percent increase in knowledge that smoking was a risk factor was reported in Watsonville, compared with less than 10 percent change in that knowledge in Gilroy, and no change in Tracy.

Respondents in Watsonville reported they ate about 35 percent fewer eggs per week, 25 percent fewer in Gilroy, and 15 percent fewer in Tracy.

"In general," says Haskell, "a hierarchy of change was observed, with the greatest improvement occurring in Watsonville, where our efforts were most intense, and the least improvement or a worsening in Tracy, where no campaigning took place.

"Preliminary results are encouraging," says Haskell. "The statistics are significant showing that substantive changes can be effected by an intensive media and instructional campaign . . . But the big question is if these figures can be maintained through the following years of the study. We are about two-thirds of the way through the second evaluation period, and it looks like we are moving in the desired direction."

The program was launched in the fall of 1972, and present data represents the changes seen between the initial survey and the first follow-up in the fall of 1973.

The project is the first time that news media has been employed in a behavior change effort at the community level, and the first attempt by scientists to evaluate whether or not the media can be used successfully for this purpose.

Dr. John W. Farquhar, professor of medicine at Stanford's School of Medicine, heads the interdisciplinary research team. Dr. Nathan Maccoby, professor of communication, is co-principal investigator. Grant support is from the National Heart and Lung Institute.

In the coming year, the researchers hope to find ways to provide longterm reinforcement in the communities, to maintain the changes in life styles already initiated. "We will be looking for ways to localize the program," says Haskell, "particularly using organizations such as the local Heart Association chapters."

A logical next step, according to Haskell, is to take the study into a larger community and try to find out if lowering risk factors would significantly reduce the level of heart disease in the community. "Our objective would be to find if the tools we have devised to reduce coronary artery disease really work," says Haskell.

"In the future, we hope to be ready to design a very effective risk reduction campaign. We should know what will work and what doesn't work, and what would be most cost-effective," he says.

Farquhar says Stanford's project represents the type of preventive effort needed to help stem the "epidemic" of heart disease in this country, which claims the lives of more than 600,000 Americans per year.

"Most deaths of people under 65 in the U.S. due to coronary disease are preventable," he said. "We believe that success in achieving substantial behavior change at the community level lies at the root of any future national campaign to reduced premature mortality from heart disease and stroke." STANFORD--Dr. Robert A. Chase, president and director of the National Board of Medical Examiners, will present the keynote address, "Dynamic Reforms in Graduate Medical Education and Licensure," at the annual Stanford Medical Alumni Day program on Friday, November 22.

Dr. Chase is former Emile Holman professor of surgery and chairman of the Department of Surgery at the Stanford University School of Medicine. An internationally known surgeon who specializes in reconstructive surgery of the hand, he is also well known for his teaching and leadership in medical curriculum innovations, medical licensure, and continuing medical education.

The National Board of Medical Examiners is a voluntary, nongovernmental examining agency concerned with testing physicians' qualifications for professional practice, and with maintaining high standards of medical education. Medical students throughout the U.S. take the Board's examinations.

Dr. Chase will speak at 1:30 p.m. following a luncheon for medical alumni, associates, faculty, and spouses at the Holiday Inn in Palo Alto.

A morning clinical symposium is planned from 9 a.m. to noon, presenting the work of Stanford's major program in plastic, reconstructive, and rehabilitative surgery.

The scientific sessions will be held in Room M106 of the Medical School. Subjects to be discussed include hand surgery, facial deformities, severe burns, body-image surgery, training rural practitioners in advanced surgical techniques, transplantation and replantation, and what Stanford is doing about surgically deprived people.

Speakers from the Stanford faculty include Drs. Robert E. Berner, Harry Buncke, Jr., Sherman Souther, Lars Vistnes, Ernest N. Kaplan, Russell Pardoe, Donald R. Laub, Michael T. B. Dennis and Robert Chase.

Luncheon reservations may be made by calling the Medical Alumni Association, 497-5594.

Mailed November 18, 1974.

STANFORD--A two-man art show featuring works by Drs. Alan R. Goldin and Joseph Kriss of Stanford University Medical School will be held Nov. 17-30 at Los Robles Gallery, 176 Hamilton Ave., Palo Alto.

A reception for both, considered proven artists in their own right, at the gallery is set for Nov. 17, 5 to 7 p.m.

Goldin, who sculpts under the name Alan Raphael, will show polyester resin sculptures that are semi-translucent, colored and abstract in nature. This will be his first show in California although he has had similar showings in Paris, Johannesburg and Capetown, South Africa. He will have shows early next year at Galerie Entermonde in Paris and in London.

Goldin, a visiting associate professor at Stanford Medical School, is on a leave of absence from the University of Capetown where he is a senior consultant in radiology.

Kriss, who is head of the Division of Nuclear Medicine, has had numerous shows in the Stanford area and his latest showing will consist primarily of abstracts and semi-abstract impressions of architectural settings, according to a gallery spokesperson. Many of the paintings are of marketplace scenes, she said, and are an extension of drawings he presented at an earlier show at Los Robles.

The gallery is open 9:30 a.m. to 5:30 p.m. Monday through Saturday.

Mailed November 15, 1974.

SCIENCE WRITERS: You are cordially invited to attend a day-long meeting scheduled in connection with the dedication of the SUMEX-AIM facility at Stanford University. The story below gives details. The description of the projects has been included for background purposes.

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos (415) 497-6911

STANFORD--Computer science and latest applications of artificial intelligence in medicine will be topics of a day-long conference at Stanford University Thursday (Nov. 14).

The occasion is the dedication of the Stanford University Medical Experimental Computer (SUMEX), the first shared national computer facility to focus on applications in Artificial Intelligence in Medicine (AIM).

Morning presentations from 9 a.m. to 12 noon will feature scientists from Stanford and other parts of the United States. The sessions will be in Room M104 at the Medical School.

Afternoon talks will be on sharing resources and intellectual efforts. Speakers include Prof. Joshua Lederberg, Nobel laureate in genetics, Vice President and Provost William F. Miller of Stanford, Dr. Thomas G. Bowery of the National Institutes of Health, and Dr. J. C. R. Licklider, professor of information science at Massachusetts Institute of Technology.

His talk will be on augmenting individual intellect by electronic communication. The sessions will be from 2 to 4 p.m. in Cubberley Auditorium.

SUMEX-AIM is funded by five-year $2.5 million grant from the Division of Research Resources of the NIH (Biotechnology Resources Branch). It is directed by Dr. Lederberg, with the assistance of a national advisory group.

The two main objectives of SUMEX, Lederberg said, are the development of the relatively new concept of national shared resources, and the further exploration of computer science applications in medicine.

SUMEX consists of a powerful PDP-10 computer. It is available to approved users through a computer-communications network.

Artificial intelligence is a part of computer science concerned with the symbol-manipulation processes to produce intelligent action. Rather than employing the digital computer as a number calculator, scientists in this field utilize the computer to reach decisions and solve problems through symbolic analysis and reasoning.

###

Following are details about projects scheduled to be presented at the conference.

Dr. Saul Amarel and Dr. Casimir Kulikowski, computer scientists at Rutgers University will describe the development of a computer-based consultation system for diseases of the eye.

In collaboration with Dr. Aran Safir, an ophthalmologist at Mount Sinai School of Medicine, they have established a national network of collaborators for diagnosis and treatment of glaucoma by computer.

- more -

22--SUMEX

The computer system, which includes an elaborate pathophysiological model of the disease, is about to be tested through the SUMEX-AIM network at three eye centers: Mount Sinai Hospital and Medical Center, New York; Washington University, St. Louis, and the Johns Hopkins University in Baltimore.

Glaucoma, in one form or another, afflicts two percent of all people over 40. The eye disease often leads to irreparable damage of the optic nerve and blindness.

The computer-based program, says Dr. Amarel, has great potential for assisting doctors and researchers in understanding the disease, and in improving its diagnosis and treatment.

Another application of the computer will be discussed by Drs. Stanley Cohen, Stanton Axline and Edward H. Shortliffe of the Department of Medicine at Stanford. They have programmed a computer to advise physicians about treatment of patients with bacterial infections.

"Patients with infectious diseases often need treatment before complete information about the bacterium is available," explains Dr. Shortliffe.

The researchers have identified clinical and historical data that serve as decision rules for the early selection of antibiotic therapy. The rules have been coded and stored in the computer so they can be used to guide the physician during consultation about choice of antibiotics.

This novel application of the computer is expected to have potential impact on the broad range of medical decisions which rest on informal judgment, according to the researchers.

Dr. Kenneth Colby, a computer scientist and psychiatrist at UCLA School of Medicine, will talk about use of computers in psychiatric treatment.

Colby has programmed computers to conduct preliminary interviews with psychiatric patients, and to simulate a patient's mental processes for other psychiatrists to diagnose.

He is using the SUMEX-AIM project to improve simulation of human belief systems, and pathological thought processes.

The idea would aid the psychiatrist not replace him. "But if the computer can be used in psychotherapy to help thousands of patients in understaffed hospitals," Colby says, "we could use it."

Other applications of artificial intelligence utilizing SUMEX-AIM involve the study of unknown organic compounds by Drs. Lederberg, Edward Feigenbaum (computer science) and Carl Djerassi (chemistry).

Still another project in collaboration with Prof. Joseph Kraut and Dr. Stephan Freer, protein crystallographers at the University of California in San Diego, seeks to infer protein structure from data obtained by x-ray defraction from crystalized samples.

Technical demonstrations for interested scientists and visitors will be from 4 to 6 p.m. at Stanford Medical Center, Room TB 105.

STANFORD — A new outdoor research station for chimpanzees born and raised in the wild has been officially opened on an isolated 24-acre tract adjacent to Jasper Ridge Biological Preserve and the Stanford Linear Accelerator Center (SLAC).

The primate center, officially known as Stanford Outdoor Primate Facility (SOPF), will allow researchers and students to observe social behavior and hormonal changes among chimpanzees in a natural setting. At present, 15 chimpanzees live on the compound, both infants and adults. However, this figure is expected to increase slightly as the chimps reproduce.

The $408,000 facility is approximately half completed. When in full operation, it is expected to have four quadrants, or enclosed areas, of about 1½ acres each. Two of the quadrants are presently open, containing trees, climbing structures, nesting areas, objects for manipulation, and other devices designed to provide the chimps with a varied and near-natural environment.

In the center of the facility is an observation tower complete with electronic equipment to record individual behavior on a daily basis. It also includes a closed-circuit television system.

The Stanford primate center is patterned somewhat after Gombe East, also known as Gombe Stream Research Center, located on the eastern shores of Lake Tanganyika in Tanzania, where researchers have been studying chimpanzees in their natural habitat since 1960.

Plans for SOPF were developed by Dr. David Hamburg, Reed-Hodgson professor of human biology at Stanford, and Jane Goodall, noted ethologist who initially ventured into the African wilds to study chimpanzee behavior.

Hamburg has noted that a high correlation exists between chimps and humans, relating to depressive and psychotic behavior. Therefore, research into nonhuman, or primate behavior, will further the understanding of depression and psychotic states in human beings.

He further noted that an upsurge in secretion of brain, pituitary, and sexual hormones at puberty may directly influence behavioral changes in both chimpanzees and humans.

In Tanzania, Goodall observed that when a chimpanzee discovered his mother had died he "sat in a huddled posture, stopped playing and exploring, ate almost nothing," and eventually lost one-third of his original body weight.

Similarly, chimpanzees in England that were separated from their peer "social group" for six months developed serious physical and mental disorders, according to Hamburg. These were characterized by clasping of the body, lack of appetite, and lack of response to stimulation.

The Stanford primate facility is being run in conjunction with the Laboratory of Stress and Conflict of the Department of Psychiatry and Behavioral Sciences at Stanford School of Medicine. Its construction was supported by gifts from private foundations and individuals.

(more)

Since the facility was delayed in opening for various reasons, all of the chimps now at SOPF were kept for two years at animal preserves in Louisiana and at Laguna Hills near Los Angeles. All 15 of the chimps were either born in Africa or in a natural setting.

The animals, hopefully, will be studied for their entire lifetimes at the Stanford compound, according to Dr. Patrick McGinnis, field director of SOPF. This will provide researchers with long-term observation of chimpanzee behavior. The researchers also plan to take urine and blood samples from some of the animals to determine hormonal changes as they age.

"The recording methods now in use at the facility are designed to note developmental changes in social behavior," McGinnis said. "These include aggression, sex, play, submissive behavior.

"No one has ever collated the relationships of hormone and behavior levels before in seminatural groups of chimpanzees," he continued. "Chimps have been studied in unnatural situations. But here there is a minimum of interference to them."

McGinnis noted that chimpanzees generally live from 40 to 60 years and may weigh as much as 170 pounds. The average chimp, he said, is three to four times stronger than man, pound for pound.

The animals are fed twice a day, including a morning meal of "monkey chow" which resembles salty, greasy biscuits. In the afternoon they are fed fresh fruit and vegetables. They drink water from spigots they have learned to operate by nudging with their mouths.

Human biology students at Stanford spend about 10 hours apiece each week at SOPF collecting data using a behavior code developed by Stanford researchers. This information is then fed to computers each month to keep a running account of individual chimps.

The primate center is large enough for the chimpanzees to get adequate exercise, avoid one another in aggressive encounters and yet permit them to live together in groups for long periods of time, as in the wild. This gives researchers a unique opportunity to view first hand the physical and behavioral development in chimps. It also provides special opportunities to see unusual development.

McGinnis, who worked four years at the Gombe Stream Research Center, noted that one of the "functions" of SOPF will also be to breed chimpanzees. These animals, which resemble man more than any other living creature, are becoming an endangered species in Africa because of continuous encroachment of their environment by man.

STANFORD--Garth is 15 years old, bright and eager to learn. But he is also shy and now he is lonely much of the time, withdrawn from his small circle of friends and from his usual daily activities.

Garth is in the hospital recovering from a severe back sprain he suffered while playing sandlot football recently. He is likely to be hospitalized several weeks and like many people before him, Garth has found hospital life traumatic and even frightening at times.

Unfortunately, until now most hospitals have been unable to give kids like Garth the psychological and recreational therapy they need. What programs are available have usually been oriented toward children or adults. The teenager has been mostly ignored.

However, at Stanford University Hospital teenage patients are now coming under a new program designed to make their stay in the hospital easier and hopefully, more enjoyable.

A small corps of Stanford University students are helping the teens by serving as volunteers in a program developed by the pediatrics department. The program, officially listed as the "Adolescent Unit Program," allows students to lend a helping hand to teenage patients. This may include playing card games, shooting a game of pool, helping with school work or just "rapping."

The program is a joint effort of the pediatrics staff and the Stanford Medical Center Auxiliary, which donated $7,832 for creation of a teen recreation area in the hospital. Some of the money was also used to purchase accessories for rooms now usually occupied by teenage patients.

The pediatrics staff was given the green light to implement the program based on studies of admission data and from interviews with teenage patients and their parents by department chairman Dr. Irving Schulman and Lee Rasmussen, formerly the clinical co-ordinator of pediatric nursing services at Stanford (she has since become director of nursing at Children's Hospital at Stanford).

This information showed that at any one time an average of 10 to 12 teenagers were placed in rooms with younger children or in adult wards, rather than with patients closer to their own age.

From this information the idea of the student volunteers evolved. Most of the handful of volunteers are medical or pre-med students and at least several of them are around each night for several hours to mix with the young patients.

They operate independently from the regular Stanford Medical Center Auxiliary whose members also work with children. The auxiliary members, however, wear uniforms whereas the student volunteers do not.

- more -

The program is being directed by Betty Lovelace, pediatrics recreation director at Stanford Hospital, and assisted by university students Susan Greenspan and Neil Resnick.

"Our recreation programs have mainly been for everyone in the hospital," Mrs. Lovelace explained, "but the needs of adolescent patients are perhaps more important. Many have a fragile self image of themselves at this age and if they break something, say a leg, it becomes a real problem to them. They have lost much of their independence by being in the hospital and now they have diminished privacy, therefore their very identity is threatened.

She noted that the more difficult cases are those teenagers who do not have any friends. In these instances she feels the student volunteers can fulfill a real need.

"In addition to specialized medical care we need to help these adolescents develop and retain their sense of identity," she said. "Illness attacks the (teenagers) 'code of conformity' and they feel a loss of independence."

To make up for this void, she says, it is important to give the teenage patient his own "personal space." As a result and as part of the adolescent program, rooms in two wards have been set aside for teenage patients to be used only by teenagers whenever possible. In addition, the rooms themselves have individual telephones, bulletin boards, closets and curtains for privacy.

Furthermore, the rec room (which can be divided from the children's playroom next door by a sliding wall partition) has been equipped with a record player-radio console, pool table, ping pong table and poker table.

"We have a comfortable place where the teenage patients can bring visitors into the hospital, a place where they can get away from the medical aspect of the facility," Mrs. Lovelace explained. "It is often awkward for them (teenage patients) to meet their friends once they are in here. That is why it is important for us to provide them with a recreation lounge."

Mrs. Lovelace said it was agreed to recruit university students for the program because it was felt they could work best with the young patients. She said using the Candy Stripers (high school girls who work as volunteers) in this instance would not be as beneficial because teenage patients tend to "over identify" with them. The stripers are more effective by being involved in other hospital programs, she said.

"We feel we must get them (teenage patients) away from this increased dependence they have for us here in the hospital because we are mother figures to them. And we think with our college volunteers we are starting to do just that."

STANFORD--A Stanford University professor says the present distribution of doctors does not meet the nation's needs.

There are acute shortages in some areas, such as general practice and pediatrics. And there are perhaps too many specialists.

"The reason is unplanned and uncontrolled medical manpower," writes Dr. John P. Bunker, professor of anesthesia, in the current issue of Stanford M.D., the magazine of the Stanford Medical Alumni Association.

How did this come about? "The medical profession has made no attempt to determine how many physicians are needed in each specialty nor have our medical schools and hospitals," says Bunker.

"And strong initiatives will be needed because the usual checks and balances of the free market system do not apply to the medical care industry."

Two forces have contributed to the present situation, according to Bunker. Medical schools aren't well prepared to train doctors for primary or first-contact medical care.

"I believe this is largely the result of the economic structure and financing of medical schools," explains Bunker. "Our faculties are made up of highly sophisticated researchers and clinicians whose sources of income are largely research grants and the practice of medical specialties.

"There is essentially no economic base for the teaching of medical students and specifically for the teaching of primary care. It is because our medical schools are funded primarily from patient care fees and research grants that our teaching programs do not meet the needs of the country."

A related problem has to do with the service needs of teaching hospitals. These provide some 25 percent of the nation's specialized care--kidney dialysis, open-heart surgery, the care of premature infants and other dramatic procedures.

"It is the young physicians in postgraduate training who provide almost all of the physician manpower and much of the skill to carry out these complicated procedures," says Bunker.

"We are training young men and women in a system providing highly specialized care. This is hardly the kind of education which prepares one to go out into general practice.

Bunker points out that the number of residencies offered in the United States presently exceeds the number of students graduating each year from medical schools. Of the 17,000 surgical residencies currently offered, only about 12,000 are filled.

-more-

"It is apparent the medical specialties could easily absorb all new physicians, leaving none for general practice," says Bunker.

How many specialists should be trained, Bunker thinks, must be geared to the long-range medical needs of the country, and not on the basis of the short-term needs of the hospital for an extra pair of hands.

Bunker urges the medical profession to assess the relative contribution of each specialty and judge where the need is greatest. ("How much surgery is needed for good health is not known, for no one has yet collected this kind of data.")

He says a national commission should be formed to set priorities. The Commission needs to be broadly representative of the medical profession, teaching institutions, and the public. The charge to this commission must include the separation of teaching priorities from the needs of hospital service, and must be coordinated with total manpower needs.

In medical education, Bunker says, the federal government needs to balance strong basic research support with strong support for primary care and teaching.

"Faculty members are only human," he notes. "They are going to set their own priorities on the basis of where their financial support comes from. They are paid primarily to do research or care for patients or both, and only secondarily to teach students.

"We have provided large economic incentives which run counter to the teaching of medical students in some areas such as primary care which now we realize we need."

Bunker is presently on sabbatical leave from Stanford as a visiting professor of preventive and social medicine at Harvard Medical School.

STANFORD--Twenty-four men have completed three and one half months of training at Stanford University Hospital and have graduated as emergency medical technicians, or paramedics.

The men, who are ambulance drivers and firemen in various cities on the San Francisco Peninsula, have been recommended to the California Public Health Department for certification to be acting paramedics.

The graduation marks the first time a large group has been trained in paramedics procedures in Northern California. The men work as firemen in Palo Alto and South San Francisco, and as employees of the San Jose Ambulance Company.

The paramedics received 200 hours of lecture and 300 hours of clinical work from Stanford physicians and nurses. The program was directed by Dr. Michael Eliastam, director of emergency services at Stanford Hospital, and supervised by Charlene Souza, RN, emergency services co-ordinator.

In graduation ceremonies held Dec. 21 at Stanford's Tressider Union, Robert Sorensen, director of the General Services Agency in Santa Clara County, addressed the new paramedics. Also speaking to the group was Dr. Robert Monlux, assistant director of public health in Santa Clara County.

The 24 graduates and their hometowns are listed below:

Dave Harry Anderson, Daly City, CA
William G. Baker, Mountain View, CA
Hal Barnes, Sunnyvale, CA
Kenneth Bass, San Jose, CA
Brian Davis, San Jose, CA
Richard Garcia, Cupertino, CA
James Geiger, Los Gatos, CA
Wallace Gonsalves, Palo Alto, CA
Bruce Hallberg, Palo Alto, CA
Carl E. Hill, South San Francisco, CA
Jerry Holbrook, South San Francisco, CA
Richard Holm, Sunnyvale, CA
Dale Hopkins, Los Gatos, CA
John Leslie, Palo Alto, CA
Al Meyer, South San Francisco, CA
Patrick O'Brien, San Carlos, CA
Gene Proietti, Palo Alto, CA
W. Keith Ramsey, Los Altos, CA
Ronald Sciandri, South San Francisco, CA
William Stridbeck, South San Francisco, CA

STANFORD--A group of students from Stanford University Medical School gathered around a cozy living room fire not long ago to chat with a woman recovering from major heart surgery.

"How did you prepare for such an operation?" they asked. "Did your doctor answer all your questions? Were you anxious?"

The students were participating in a new class at Stanford Medical School offered to medical students and others in health and social sciences. The relaxed meeting in the patient's home was quite different from the students' normal work in a hospital clinical setting or a large lecture hall.

Each week during the Fall quarter, about 16 students met with a patient and often his family, either in a faculty member's home, the patient's home, or around a library table in the Medical School's Department of Family, Community, and Preventive Medicine.

Purpose of the class is to expose students to the impact that medical illness has on patients and their families, emotionally, financially, and in other ways.

Dr. David Kaplan, director of clinical social work at Stanford, and Leona McGann, assistant professor, indicate their aim is "to introduce students to today's health care system through the eyes of the patient and his family."

They cite the need for students to learn vital communication skills, and to understand related problems of patients, particularly those with long-term illnessess.

The students talked with patients whose illnessess were crises in their lives: a man on renal dialysis; the parents of a baby who was in the intensive care nursery for an extended time; a woman with breast cancer and her husband; a stroke patient in a convalescent home; a young girl paralyzed by a spinal cord injury.

Students rate the class highly. "It's more realistic and concrete. It's valuable because it's people oriented."

John Sanchez, third year medical student, has been trying to interest others in a similar class to be given in the Winter quarter. "This class is refreshing," he says. "Our experiences have been in the scientific lecture or the clinical setting, and we don't have much exposure to the humanistic side of medicine.

"We learn to treat muscle atrophy, for example," he says, "but we don't know about the social and psychological problems of the illness that can determine whether the patient takes his pills or not, or whether he will stick to his diet....I was never aware of these problems before. It's a different side of the coin."

-more-

222--Students

In talking with the heart patient recently, students inquired about symptoms, current exercise, whether she can tell if she is getting tired.

The patient passed her hospital and doctor bills around the room. Students reviewed the long itemized statements, asked what "customary charges" meant, what part insurance and Medicare would pay. One student, perplexed over a bill, shook his head. "Why don't they write down what it means?" he asked.

The financing of medical care is emphasized, with the aim of informing students about the costs of tests and procedures, for example, and their impact for the patient.

Often the students just listened. "I couldn't sleep--it was too uncomfortable. I don't remember the time in the intensive care unit; it's all a blank."

And they listened as a family member noted how hard it is to talk about fears before surgery and reactions afterward: "Her hands were icy cold, and when she could talk, her voice sounded so different. It's hard to know what to say."

Besides the patient, various members of the medical team including nurses, physicians, and social workers were often present at class sessions. Tape recordings of interviews with patients were also used.

One student commented, "This course showed the need for a humanistic approach to patients, and that those involved in patient care should be understanding and have concern beyond the physical problems."

Another says that "probably the most valuable knowledge I gained is the importance of keeping the patient informed, and of letting the patient be active in treatment and decision-making."

Besides future physicians, the class is open to graduate and undergraduate students in health fields and from the social sciences. It has already reinforced the career choices of several undergraduate students in the human biology program.

According to Dr. Kaplan, similar classes are being planned for the future to give students the opportunity to observe doctor-patient communication.

STANFORD — An 18 month-old who appears to be deaf; a two-year-old who isn't talking; a three-year-old who fails to follow directions or can't talk clearly. . . .

Commonly, children with such communications problems have a high risk for academic failure when they reach school age.

But dramatic changes have been seen in such children following the first year of an experimental preschool at Stanford, according to Dr. Kathryn R. Beadle, director of the Stanford Speech and Language Clinic.

The new program stresses early identification of children with such problems, then specialized teaching in a group situation, rather than individual speech therapy. The class was held five mornings a week for the nine-month academic year. Its development was aided by the Luke B. Hancock Foundation and will be continued by the University this year.

Of the 10 children who began the class in 1973, six entered the public school system this fall, four of them in normal classes, and two in combined first grade with special help. The others, mostly younger children, are repeating the preschool program this year.

All of the children showed dramatic improvement in understanding and behavior control by the end of the year, Beadle said. Socially they had learned to enjoy each other, she said, and to learn in small and large group settings. There was a noticeable increase in talking, and their speech was easier to understand. Initial tests showed that all the children had certain problems in common: difficulty following directions or understanding speech; poor concentration, which Beadle describes as both an auditory and visual focusing problem; eye-hand coordination problems; and poor speech.

Without help, she notes, 70% of children with such symptoms would have difficulty in school, despite normal intellectual potential.

Speaking before a meeting of the American Speech and Hearing Association recently, Beadle noted that the aim of the preschool is to increase and improve the children's verbal language skills so they will be better prepared to enter school, correcting problems as early as possible.

The class does not focus on speech as such, but rather on a child's total development, providing varied experiences to help improve concentration, balance, physical coordination, perception, and understanding of speech.

"Our framework for the program is based on the concept of speech as the primary organizer and regulator of experiences. Our emphasis is on listening, then using speech as an aid to learning. We feel communication skills will then follow," says Beadle. (more) 12/11/74 cr

speech clinic 2-2-

A key element in the program is the children's social interaction with each other in a varied curriculum.

"Speech and language does not develop in a vacuum, nor is it an independent process. . .normal children are not taught how to talk. We may influence vocabulary and grammatical development, but the generation of language is essentially a process of spontaneous combustion.

"The group experiences offer more natural encounters than individual therapy, plus the incentive of children with whom it might be more fun to communicate," she says.

In addition, teachers and children constantly verbalize what they are doing. Teachers also help the children to verbalize feelings. Beadle stresses the importance of building positive self-images. "A major part of our intervention is to motivate the children by demonstrating that we consider them special and valuable."

The program also involves using the normal learning stages of children, which include coordination. Early language development is thought to be tied to sensory-motor development.

To aid coordination, the children do warm-up exercises, build obstacle courses with tires and tables, roll balls, throw bean bags. They make up dances and play active as well as verbal games.

They closely watch their teachers (usually three for the eight to 10 children in the class) during a group lesson on numbers or language. There are art projects, science lessons, story time, and sharing. For children who are ready, skills to prepare them for reading and writing are taught.

Parents are closely involved and considered an important part of the program. There are weekly mothers meetings as well as monthly meetings for mothers and fathers as a group. Homework booklets are sent home each week to review the curriculum and encourage parents to work with their children.

Dr. Beadle stresses the need to follow the children through the next several years to note if improvements continue. She urges continued work on developing an effective teaching program for such children, particularly since public schools may soon become responsible for all children three years old and over.

FOR IMMEDIATE RELEASE

STANFORD — Portions of the intricate printing press that cells use to reproduce their genetic information have been deciphered by biochemists at Stanford University School of Medicine.

The work is expected to help scientists understand how normal cells grow and divide and why cancer cells multiply so rapidly.

Scientists know that the cells' hereditary machinery can produce exact copies of itself to perpetuate the species. But they have only recently begun to sort out the individual parts of that machinery.

With the identification of some switches that regulate the apparatus, the Stanford team was able to reconstruct three systems in the test tube that seem to represent the duplication mechanisms of cells themselves.

Their research was reported in the December 13 issue of *Science,* the journal of the American Association for the Advancement of Science. Authors are Randy Schekman, a graduate student in biochemistry, Dr. Alan Weiner, formerly a postdoctoral fellow in the Department of Biochemistry, and Dr. Arthur Kornberg, professor of biochemistry. The work was supported by the National Institutes of Health and the National Science Foundation.

The cell factory is directed by a remarkable construction manual known as DNA (deoxyribonucleic acid), explained Kornberg in an interview. This manual has two main functions. It contains the chemical instructions for manufacturing the molecules that run the cell. In addition it serves as a template to duplicate itself so that the cell offspring will have the same manual as their parents.

"At times, something goes wrong, and the construction manual isn't duplicated correctly," Kornberg noted. "If we don't know the working parts of the press that duplicates the manuals, we can't step in to make repairs."

Several years ago, scientists thought they understood the press. They had found an enzyme called DNA polymerase which could copy the manual faithfully by linking the building blocks of DNA in proper sequence. In 1967, a team led by Kornberg used this enzyme to create the first synthetic DNA molecule that was biologically active.

It turned out that the duplication process was actually a more complicated series of events involving several different enzymes. The laboratory techniques used to prepare the man made molecule in 1967 did not faithfully represent the cell apparatus.

"We thought then that DNA polymerase is only one component," Kornberg said. Although it can string together the DNA alphabet without error, DNA polymerase is apparently blind to signals that begin duplication.

(more)

For the last few years, investigators at Stanford and in other laboratories have been searching for the missing pieces of the cell duplication machinery. Two obstacles had to be overcome first. Experiments had to be designed that could detect the unknown units. Then these units needed to be put together in a manner that permitted them to function efficiently in the test tube.

Through major efforts in several laboratories, some of the agents that initiate DNA synthesis have been identified, and the properties of DNA polymerase have been more precisely defined. The Stanford team has successfully assembled those components to perform in the laboratory. (Drs. Sue Wickner and Jerard Hurwitz at Albert Einstein College of Medicine in New York reported similar results in the October issue of the *Proceedings of the National Academy of Sciences*.)

"Our results are an encouraging beginning," said Kornberg. "We now have the outlines of the major parts of the duplicating machinery. With intensive and sustained efforts, we can locate additional pieces to fill in the gaps. Painstaking detail is involved, but it is necessary if we are to fully understand the cell."

* * *

Patience and dedication are the trademarks of such research. Every new finding increases knowledge and contributes to scientific advancement.

Scientists knew about the construction manual for living things for over 80 years before they began to comprehend its language. Since James Watson and Frances Crick determined the helical structure of DNA in 1953, scientists have gradually been able to translate its intstructions into chemical language. Their progress has been step by step.

In 1959, Kornberg successfully created DNA in the test tube. Although this DNA had the physical and chemical properties of the natural molecule, it was biologically inactive. It took another eight years to manufacture a molecule that could reproduce. And now, some 20 years after the basic DNA model was defined, the scientists have started to unravel the secrets of the intricate apparatus that allows DNA to perpetuate itself generation after generation.

The primary tools for the Stanford studies were tiny viruses. It would have been futile to try to unravel the operations of larger life forms first. Animal cells contain chromosomes made up of thousands of genes. Each gene in turn is a DNA segment that has about 1,000 building blocks. Viruses, on the other hand, have chromosomes a thousand times smaller than a bacterial chromosome and hundreds of thousands of times smaller than any animal chromosomes.

The researchers used three viruses that infect *Escherichia coli*, a generally harmless bacterium found in the human intestine. These viruses subvert the bacteria duplication system to propagate themselves at their host's expense. They are the same size and complexity of some viruses that produce cancer in animals. Cancer viruses invade the cell and distort cellular operations in a way that causes the cell to grow out of control and become malignant.

(more)

"By studying how these simple creatures go about their business, we can figure out how bacteria manufacture chromosomes," said Kornberg. "From our knowledge of evolution and previous experience, our findings are likely to apply to animal cells, and provide major clues for human cells."

Nature guards her most fundamental life process with elaborate control signals. Their elucidation can aid in the diagnosis, treatment, and ultimate prevention of a range of diseases that stem from a failure in the duplication process, according to Kornberg.

"Much of the cancer mystery must lie in the control of DNA synthesis, a process required in young growing cells, but malignant in mature ones," he said. Normal liver cells in an adult, for instance, do not produce DNA. Yet when these liver cells become cancerous, the duplication cycle is turned on again and DNA synthesis proceeds rapidly.

The forces that govern DNA synthesis may also hold the key to psoriasis, a common skin disorder that produces itching, scaling, and redness. It is thought to be caused by a defect in the mechanisms that regulate the growth of certain skin cells.

"It seems essential that we understand normal DNA synthesis to understand the proliferative or abnormal response," pointed out Kornberg. "If we want to use drugs to interrupt the process when it is proceeding at an undesirable rate, we have to know at what stage to intervene with the appropriate medication."

One of the viruses employed by the investigators was Phi X 174, which Kornberg's group used in 1967 to manufacture the active DNA. Other bacterial viruses they used were M13 and G4. Their chromosomes, which contain only eight to ten genes, are relatively easy to copy. The DNA molecules are single stranded circles which are converted to double stranded structures when the virus invades the cell. These strands separate and each one serves as a template for generating more DNA, using the cell system.

Every reaction of the duplication process was carefully monitored. The scientists found that each virus utilized a distinctive system with highly specific enzymes to duplicate its DNA. They are convinced that the three systems identified are similar to those the cell uses to duplicate its own genetic elements. It seems likely that additional systems remain to be discovered, they said.

Components of the individual systems were isolated and purified. Then the systems were reconstructed in the test tube. DNA synthesis was optimal when all parts of any system were assembled. It was reduced if a single component was omitted. Specialized methods were used to measure DNA production.

In spite of their individual requirements, all three systems operate with similar mechanisms. Duplication can be divided into three stages: initiation, elongation, and termination.

Initiation is the most involved. Specific signals in each system promote the formation of spe special priming runs that turn on duplication. Once the cycle is started, DNA polymerase extends the new DNA chain according to template directions. After the template has been copied completely, the priming runs are excised and the DNA circle is sealed.

FOR IMMEDIATE RELEASE

STANFORD — A psychiatrist and a patient are talking frankly about each other.

He is a professor at Stanford University. She is a young, talented writer whose desire to help herself was matched by her determination to hate herself.

Then she entered treatment with Dr. Irvin D. Yalom. They agreed to write separate journals of each of their sessions which they would exchange every six months.

The result is *Every Day Gets a Little Closer* (244 pages, Basic Books, New York, 1974, $8.95). It is the first book to share the dual reflections of psychiatrist and a patient whose pen name is Ginny Elkin.

"There is a little demon within Ginny stealing the meaning and pleasure from everything she does," Yalom's diary begins. "At the same time she tends to observe herself and romanticize her plight in a tragic way.

"She flirts, I think, with the vision of herself as Virginia Woolf who one day will fill her pockets with rocks and walk into the ocean."

And Ginny writes: "I felt like a dilettante in your office, at first. You were asking me what was on the agenda, what I wanted to happen. I have a long history of not answering or taking questions seriously."

For two years, Yalom and Ginny exchange their reports in the hope of therapeutic benefit, frequently adding afterthoughts, interpretations and associations they hadn't voiced during the sessions.

Here is a sample of selected quotes, not as they appear in the book, but juxtaposed to give a rare glimpse of the relationship between patient and therapist and the progress of treatment.

Yalom: She looked very well today, with a neat skirt, blouse and tights, and her hair almost brushed, but she was clearly very shaky. . . .

Ginny: The session was very important to me. I think I managed to talk and think and feel through my tears.

Yalom: I was being good for Ginny today. I worked hard and helped her to get at some things. I wonder if I wasn't just trying to impress her, trying to make her fall in love with me. Good Lord! The ludicrousness of it. Here I am trying to help Ginny with survival problems and I'm still burdened down with my own petty vanities.

Ginny: Something might happen if I were more natural looking. So I left my glasses on. Something might not happen though.

Yalom: I was really impressed with how pretty she looked today. I was looking at her more in profile. There have been times before. . .when I considered Ginny rather homely, and yet today I saw her quite lovely.

Ginny: I was inside the car [with a friend] discussing the *Freedom of Sexual Surrender,* a book which discredits clitoral orgasm. . . . So in the middle of this sexual talk, you and your wife crossed the crosswalk in front of us, like a stunt in a TV comedy.

(more) 12/9/74 cr

Yalom: An odd sort of session.

Ginny: I know I want too much attention, undivided attention.

Yalom: I feel we moved into a new and fertile territory today. She wants me to treat her like an adult and I said to her, fearing that I was being a scolding parent, that to be treated like an adult, one has to act like an adult. I think this tact is helping her to relate to me more as a grown-up person.

Ginny: Oh, God, yesterday's session was the first that I began to feel my own methods.

Yalom: I think I've been too intrusive in forcing my values on Ginny. I was too authoritarian today. . . .

Ginny: It's hard for me to remember what happened [at the session].

Yalom: I told her I would feel so much closer to her if she could come into the interview and give me hell if she were upset about something that I did wrong.

Ginny: I disliked the grin on my face whenever I answered one of your questions.

Yalom: There was a time today when I felt that Ginny had practically nothing to say to me, indicating that maybe she's better, maybe she'll be discontinuing therapy before long.

Ginny: Somehow I felt like I had taken several steps closer to a starting line from where we could begin.

Yalom: Today I felt for the first time I've left therapy too open-ended. Maybe I should set a termination date.

Ginny: When you asked me about goals I realized how outside any self I feel. I gave civil answers. I might as well have been talking to a high school guidance counselor.

Yalom: A weird vaudeville-like hour.

Ginny: I thought yesterday we were just like two friends getting together.

Yalom: One of the dullest hours I've spent.

Ginny: I forgot what we talked about in session.

Yalom: One up, one down. Ginny really is right. The sessions do alternate strikingly in their meaningfulness.

A few months later the sessions between Dr. Yalom and Ginny continue, but something has been added.

Ginny: This session was very helpful to me. You took a more active part.

Yalom: Something very different happened today. Ginny brought Karl with her [the young man she had been living with].

Ginny: It was so funny to see you round the corner ready to welcome me, and then get surprised by seeing Karl. I had always thought I was protecting you from Karl's abuse. But he thought you were wonderful, intelligent. He thought it was weak of me to have considered not taking him. I really enjoyed it and was grateful to you. You seemed to be my true friend.

Yalom: Ginny wants Karl to come again next week and perhaps the week after. She realizes as I do that the joint sessions are tremendously important.

Ginny: The night before in a surge of warmth and truth toward Karl, I had started to broach the subject of my sex problems. I tried to reassure Karl that every night I don't lie there at the edge of destruction. Now there is a strong undertow. I'm coming face to face with my own resistance.

Yalom: The last hour. I feel very shaky, very sad and very moved. When I stopped the hour and said, "Well, I guess the time has really come for us to say good-by," both of us remained frozen for a few seconds. She started to cry and said, "You're so wonderful to have done this for me. . . . She left the office, not a borderline character disorder. . . . She left as Ginny and I will miss her.

Ginny: I admit I'm capable now of leading a normal life. I feel okay.

Was Ginny cured? Yalom says the reader will have to judge for himself. But gone are the night panics, the frightening dreams, the migraines. And Ginny has now terminated her relationship with Karl which was growth-retarding for both parties.

Yalom observes, "The 'art' of psychotherapy establishes its own truth transcending objective scientific analysis.

"The truth is a beauty that Ginny and I experienced. We knew one another, touched one another deeply, and shared splendid moments not easily come by."

STANFORD--A new technique for predicting which heart transplant patients will reject their new heart severely and which will have a smooth clinical course has been developed by a Stanford University heart research team.

The technique has predicted accurately the clinical course of the last nine patients who received new hearts at Stanford University Hospital. It is being used to help screen potential heart transplant recipients.

The procedure is based on the recent finding that immune systems function differently in individuals, and that white blood cells are responsible for this variation.

Patients whose white blood cells mount a vigorous attack to a test panel in the laboratory, also react violently to a new heart. These patients have serious rejection episodes and are considered hyperreactive. Patients with fewer active blood cells have fewer rejection problems and do better.

A study of 11 heart transplant patients in 1972 and 1973 is reported in the November issue of Transplantation, the journal of the Transplantation Society. Authors are Drs. Alan Coulson, Fran McMillan, Randall Griepp, Edward Stinson, Eugene Dong, Jr., and Norman Shumway. Virginia Geitman is also working on the project now.

It is not surprising to find a variation in immune activity, noted Coulson. Many organs--including the brain, thyroid gland, bone marrow, even the stomach--are known to vary functionally from one person to another.

"Eventually we may use this method to help the surgeon determine whether or not to do a heart transplant operation. In theory, such screening techniques could be done before other organ transplant operations also," Coulson added.

For the screening procedure white blood cells are separated from the blood of heart recipients prior to surgery, before they receive any immunosuppressive therapy to prevent rejection. They are mixed in a laboratory tissue culture with several stimulants, including standard immunosuppressive preparations and donor white cells.

A standard stimulant added to the tissue culture provokes an immune response that results in a transformation of the recipient white cells. The greater the number of cells transformed, the higher the immune activity. The data are analyzed on a computer and a response profile of each patient is drawn up.

In the study, the screening results were compared to the postoperative course of the transplant patients. The number, frequency and severity of rejection episodes were scored.

A low response profile carried a good prognosis, the investigators found. A high response profile was associated with a poor post transplant course.

Of the 79 heart transplant patients operated on at Stanford, 28 are living. The survival figure for the heart recipients in the past year has been 50 percent. ### Mailed Tuesday, December 3, 1974

STANFORD--Dr. Paul F. Basch, associate professor of family, community and preventive medicine at Stanford University School of Medicine, has accepted an invitation to visit the People's Republic of China in April.

An expert in international health, Dr. Basch will visit China as a member of the schistosomiasis delegation.

The trip is arranged by the committee on scholarly communication with the People's Republic of China, sponsored by the American Council of Learned Societies, the National Academy of Sciences, and the Social Science Research Council.

The delegation will consist of scientists in the fields of parasitology, epidemiology, immunology, public health, and chemotherapy. The visit is part of a series of exchange programs arranged in collaboration with Chinese scholars, he said.

Dr. Basch is an expert on parasitic diseases, with special emphasis on schistosomiasis. He is also interested in international measures in disease control. He teaches courses in international health, medical parasitology and epidemiology in the practice of medicine.

STANFORD--Union representation elections for five categories of Stanford University Hospital and Clinics employees will be held April 10, 11, and 12 at the Hospital following a consent agreement reached Friday (January 24).

The agreement between the Hospital and five labor organizations culminated nearly three months of formal hearings before the National Labor Relations Board (NLRB).

According to John J. Schwartz, counsel for medical affairs, employees will cast ballots in the following five groups: 1) allied health professionals, 2) service, technical, patient care and plant clerical, 3) pharmacists, 4) maintenance, and 5) interns and residents.

Negotiations, Schwartz added, are in progress for an agreement to hold a separate election on the same dates for Licensed Vocational Nurses.

Registered Nurses will not participate in the election because they are already represented by the Committee for Recognition of Nursing Achievements.

Secret ballot elections will determine whether a majority of employees in each group wishes to be represented by one of the unions on the ballot or no union at all.

Locations and times of the election will be decided by the NLRB regional director after consultation with the parties.

The labor organizations are United Stanford Employees, Local 680, Service Employees International Union, AFL-CIO; Stanford United Medical Technologists; Stanford University Medical Center Engineering Department Association; Stanford University Housestaff Association; and Engineers and Scientists of California, AFL-CIO.

***

Following is a summary about the agreement, the employees and organizations involved:

--Allied health professionals except for registered nurses and doctors will choose to be represented by Stanford United Medical Technologists, United Stanford Employees or no union at all.

The professional category covers about 300 people and includes licensed medical technologists, blood gas technicians, pulmonary physiology technologists, dieticians, nutritionists, physical therapists, recreation therapists, clinical psychologists, social workers and social worker assistants, speech and hearing clinicians, anaplastologists, architect/planners, cardiovascular engineers, computer digital engineers, industrial engineers and project engineers.

--About 1,000 service,technical, patient care and plant clerical employees will vote for representation by Engineers and Scientists of California (an affiliate of Marine Beneficial Association), United Stanford Employees, or no representation at all.

- more -

22--Elections

--About 15 pharmacists and pharmacy interns will choose whether to join for representation with the allied health professional or the non-professional categories as well as choosing whether they will vote to be represented by Stanford United Medical Technologists, Engineers and Scientists of California, United Stanford Employees, or have no representation.

--Eighty maintenance employees now represented by the Stanford University Medical Center Engineering Department Association will decide whether to be represented by the Engineering Association, United Stanford Employees or no union at all.

Maintenance employees covers those working in the support services/facilities department and includes carpenters, electricians, locksmiths, painters, masons/plasterers, mechanics, plumbers, maintenance engineers, preventive maintenance personnel, gardeners, laborers, tool and crib attendants, biomedical electronics technicians and assistants, operations center personnel, and communications operators.

--Some 360 interns and residents will vote by mail ballot to choose between Stanford University Housestaff Association or no representation. Schwartz said interns and residents will receive their ballots by mail on April 1 and must return them by April 11. Eligible to vote are residents and interns with contracts of appointment in effect as of December 28, 1974.

To be eligible to vote, all permanent part-time employees and all relief recurring and relief one-time employees must have worked in a classification described for at least four of the six consecutive payroll periods preceding December 28, 1974 for no less than 80 hours. The cutoff date for similar employees on the University payroll is December 31, 1974.

Managers, supervisors, and guards as defined in the National Labor Relations Act are excluded from voting.

STANFORD--The muscle structure of a common round worm may give researchers clues to understanding muscular dystrophies that cause gradual paralysis in humans, according to a Stanford scientist.

Studies in the nematode, a round worm, have shown for the first time that molecular defects in the structure of the muscle tissue can lead to defects in the function of that muscle.

The research is being done by Dr. Henry Epstein, assistant professor of pharmacology at Stanford University School of Medicine, and by Drs. Sydney Brenner and Robert Waterston and by J.N. Thomson, all of the Medical Research Council Laboratory in Cambridge, England. Their work is reported in the recent Journal of Molecular Biology, and in Nature, a British scientific journal.

Normal muscle viewed end on end, consists of a lattice of thick protein filaments surrounded by thin protein filaments, all in a very definite unvarying pattern. But the muscle of certain mutant nematodes who have been paralyzed by early exposure to high temperatures is conspicuously different, with thin filaments set at all angles, randomly, instead of being in parallel.

Scientists are investigating whether the fault lies perhaps in some protein which acts during the assembly of the muscle components--whether some slight alteration in the chemical composition of the enzyme prohibits it from performing its function as an enzyme.

Another set of mutant nematodes studied have severe paralysis at all temperatures and throughout their lifespan.

"We traced the genetically defective muscle back to disruptions in the filament lattice-work responsible for contraction, and to the myosin molecule, which is the "engine" for contraction," says Epstein.

Errors in the myosin molecule can prevent formation of normal thick protein filaments which in turn prevent development of normal structure and function within the muscle, according to Epstein.

Scientists who have been working on dystrophic muscle for many years have not been in agreement whether defects are in the nervous system or in the muscles. Epstein feels that the current work may help give future research more direction, by pinpointing certain defects in the muscle molecules.

Also, he feels that techniques developed for analyzing the contraction proteins of round worm muscles could be applicable to study of muscle diseases in humans.

Besides muscular dystrophy, the basic research hopes to further scientists' understanding of how the heart muscle works in cardiovascular diseases and diseases of the arteries.

The work is supported by grants from the Muscular Dystrophy Associations of America, and the American Heart Association, National Genetics Foundation, and National Institutes of Health.

SCIENCE WRITERS: Additional technical information about the Stanford medical pion generator has appeared in the fall issue of *Stanford Magazine*. Reprints as well as photos are available on request if not included with the story.
FOR IMMEDIATE RELEASE
STANFORD —

Stanford University scientists Friday, Jan. 24, announced they had developed a new tool for cancer treatment, and would soon begin testing it in living cells and laboratory animals.

Called a medical pion generator, the new tool will use a stream of pimesons, subatomic particles generated by a high-energy accelerator, to kill cancer cells with miniature nuclear explosions.

The experiments will take three to five years before the treatment is available to patients, but if pion beam therapy becomes a reality, it would mark a milestone in cancer radiotherapy, they pointed out.

It would enable physicians to attack more successfully some cancers now difficult to treat. These include cancers of the mouth and throat, certain tumors of the brain and lungs, or those which presently go untreated because they are resistant to conventional radiation.

The pion generator is the brainchild of Drs. Malcolm Bagshaw and Henry S. Kaplan of the Department of Radiology, and three members of the Physics Department—Prof. H. Alan Schwettman, Dr. Douglas Boyd, and Prof. William Fairbank.

The five men have worked for nearly four years to bring the pion generator to this stage of development.

Stanford's team is one of four groups in the U.S., Canada, and Europe exploring the potentialities of pion therapy today. At least two others are expected to begin treating patients ahead of Stanford, but Stanford's represents the only effort to develop a machine which could be installed in a hospital, where it will serve the maximum number of patients.

The Stanford researchers announced their development at a two-day conference on technical aspects of pion radiotherapy and future clinical applications at Rickey's Hyatt House in Palo Alto Friday. The conference will be concluded Saturday.

What is pion beam therapy and why is it so exciting to radiotherapists? Pions (also known as pimesons) are small particles found in the nuclei of atoms. They make up the "glue" or "cement" that holds protons and neutrons together in the nuclei.

Pions can be generated by the newest, most powerful high-energy particle accelerators of the type used in nuclear research. When pions strike living tissue, they slow down and are eventually captured by nuclei in atoms of living cells. A nucleus which captures a pion explodes. This miniature nuclear explosion is known as "star formation."

(more) cr 1/23/75

"Because," Bagshaw explains, "the nuclear fragments produced in this explosion cause such great destruction, pion therapy is expected to be about three times as effective in killing tumor cells as X rays giving a comparable radiation dose."

Furthermore, pions can be stopped quite precisely in a target region by varying their momentum. Thus, tissue damage can be confined entirely to the tumor volume. X rays, on the other hand, are attenuated gradually and many pass through the body, damaging healthy as well as malignant tissue.

Another advantage of pions is that the radiation released during the miniature atomic explosion within the cells can be detected, and therapists expect to see exactly where cell destruction is taking place.

Finally, the Stanford medical pion generator involves a radical new approach for delivering cancer killing radiation which should further improve treatment with little or no damage to nearby healthy organs or other tissue. Dr. Kaplan calls this approach "absolutely unique."

Schwettman said that the powerful superconducting magnet techniques employed in the system design made it possible to construct a pion generator of maximum efficiency and great simplicity. The device is about 60 times more efficient in collecting pions and delivering them to patients than conventional channels. ("Channel" is the name physicists give the device, but the radiotherapists who will be using it have named it the medical pion generator.)

The generator is a large tank about 17 feet long. It is the crucial part of the system. Its interior consists of 60 individual superconducting magnet coils at each end, placed like photographic slides in a circular slide tray. In this case the tray is in a vertical position.

The machine is connected to a 500-Mev linear accelerator. Pions are produced when the powerful accelerator beam hits a titanium target. The pions produced in this way escape from the target in all directions, are collected by the magnets, and are channeled into 60 separate beams.

At the other end of the tank a second set of magnets takes the 60 beams and aims them at the patient. Slits along the circumference of the tank, midway between the ends, can be adjusted to change the intensity of the pion beams striking the patient's tumor.

The generator is cooled by liquid nitrogen and liquid helium to make the wire windings of the magnets superconductors.

Work on the pion generator, the scientists said, has also spawned three new instruments essential to the pion system. They were developed by Boyd in the High Energy Physics Laboratory.

One instrument measures the density of tissues that pions must enter. This is important because knowing the density, radiotherapists will then be able to adjust the momentum of the pions so that they will stop and be captured at the exact location of the tumor.

(more)

A second instrument will be used to monitor the actual pion stopping region during treatment. When pions are captured in the tumor and explode they give off gamma rays which can be detected. With this type of information, radiotherapists can be sure that every day's treatment utilizes a stopping region which coincides with the location of the tumor. A third instrument developed by Boyd will be used to pinpoint the location of the tumor itself.

The treatment approach grew out of the way Schwettman and Fairbank designed the pion generator "It really opened the way to a new kind of dose distribution in the patient," said Kaplan.

The Stanford pion generator was designed and built in the High Energy Physics Laboratory with approximately $1 million in grants from the Research Applied to National Needs program of the National Science Foundation The planned experiments with living cells and laboratory animals will be supported with new funding from the National Cancer Institute.

If medical pion generators like the current prototype are installed in a hospital, four could be operated off a single accelerator. Such an accelerator for hospital use has not yet been built. For testing purposes, the present pion generator is energized by a relatively large and expensive accelerator constructed originally for physics research.

But the scientists are confident that once the pion therapy is proven superior to conventional radiotherapy, a scaled-down version that would fit into a hospital could be constructed.

The accelerator, four pion generators, other equipment and the building might cost about $8 to $10 million at today's prices, which isn't far from building and equipping a radiotherapy facility in a large medical center, the scientists said.

Fairbank feels the medical pion generator should make radiotherapy much more like surgery. Not only will cancer therapists have a much better "knife" at their disposal—but for the first time they will really have "eyes" to see where it is cutting.

STANFORD--New prices representing an average three percent increase in room rates and services will be put into effect tomorrow (Jan. 15) by Stanford University Hospital.

The new rates will be $104 for ward, $113 for semiprivate room, and $127 for a private room.

The rates were approved by the Hospital Board of Directors at their regular meeting Monday (Jan. 13).

In addition, the directors approved a 15 percent increase in daily Intensive Care Unit charges, from $317 to $364.50.

Paul Hofmann, director of the hospital and clinics, said the new prices reflected these factors:

--an extraordinary increase in malpractice insurance premiums.

--an increase in patients with acute conditions requiring 24-hour coverage by one or two registered nurses per patient in the Intensive Care Unit.

--an increase in the number of patients covered by Medicare and Medi-Cal (about 40 percent of Stanford's patients are covered by these plans which pay hospitals on the basis of cost only, not taking into account that hospitals have requirements for replacement of equipment and facilities).

--increases in the cost of supplies, equipment and utilities due to inflation.

Hofmann said Stanford hospital participates in the California Hospital Association's insurance program. All member hospitals were notified in December that their malpractice premiums would go up in 1975. Stanford's premium, based on the number of beds, doctors, residents, and patients treated, will be more than $1 million in 1975, a 100 percent increase.

"Stanford hospital with its highly specialized services for patients, cannot continue to defer urgent capital equipment acquisitions without compromising seriously its ability to maintain an adequate standard of patient care," Hofmann said.

He said the inadequacy of government reimbursement, the increasing intensity of the care provided by Stanford hospital, escalating inflationary prices, and the continued pressure for increased salaries have their inevitable effect on institutional costs.

Hofmann emphasized that the price increase would have been higher if cost reductions had not been implemented in several major areas of the hospital operations.

Stanford hospital raised its rates in July, 1974. The effect of the price increase had averaged 11.5 percent overall. More than 99 percent the hospital's income comes from patient revenues. The Hospital has no tax support or endowment income.

FOR IMMEDIATE RELEASE
STANFORD –

Maestro Artur Rubinstein and Nobel Laureates Linus Pauling and Joshua Lederberg will join others eminent in the sciences and humanities to discuss "The Majesty of Man" in Dinkelspiel Auditorium on the Stanford campus at 7:30 p.m. Friday, Jan. 24.

Sponsored by the Office of Postgraduate Medical Education of the Stanford School of Medicine, the program proposes to discuss optimistic views of man and his future in a kind of "celebration" of mankind's humanity and creativity.

A scientific portion of the program will deal with how the human brain is put together, how it functions, how its performance is modified by experience, how it differs from those of lower organisms.

New findings in this scientific area will be presented by John G. Nicholls, M.D., Ph.D., professor of physiology at Stanford, and by Gilbert S. Omenn, M.D., Ph.D., of the University of Washington School of Medicine in Seattle.

Dr. Nicholls, a neurophysiologist, is studying how nerve cells work together to produce organized behavior. He will discuss the structure and function of the nervous system. Dr. Omenn, involved in recent research in genetics and DNA, will report on his findings indicating the biochemical uniqueness of the human brain.

Maestro Rubinstein, 86, world renowned pianist, will join a panel to discuss more informally the creativity of man. Recognized as a musical genius at an early age, Rubinstein is expected to discuss his thoughts about talent, genius, creativity, and their encouragement.

Joining him will be Linus Pauling, an energetic teacher and investigator whose studies of how molecules are put together formed the basis of chemistry and biochemistry of this era. Dr. Lederberg, professor and chairman of the Department of Genetics at Stanford, is recognized internationally for his pioneering work in the recombination of bacterial cells, and for his more recent work in molecular biology.

David Hamburg, M.D., professor in both biological sciences and psychiatry, will moderate the discussion. Topics are expected to include conditions favorable to creativity, the idea of increased mental achievement with age, the importance of early development, and the uniqueness of man.

According to Dr. Edward Rubenstein, associate dean for postgraduate medical education at Stanford, the program seeks to emphasize the creativity and humanity of mankind, focusing on man's positive aspects and potentials. "As we approach the truth about nature, we find that man is more unique than we have realized, capable of enormous mental achievements," says Dr. Rubenstein.

"I think people have heard enough about the world's problems. . . . We should end this era of misanthropy. Despite the problems, man has been extraordinarily constructive."

Because of limited seating, admission to the program is by ticket only. Tickets are free of charge, but must be reserved in advance at the Tresidder ticket office on campus, 497-4317.

STANFORD--Stanford University Vice President for Medical Affairs Clayton Rich said Monday that a budget balancing program for the School of Medicine is necessary for the next five years.

In a letter to the faculty, Rich said that a revised financial forecast for the Medical School shows "a considerably more serious trend toward deficit than earlier predictions."

The previous forecast had concluded that the Medical School was relatively well off compared to the rest of the University, and that "we had a couple of years to make adjustments to bring about financial equilibrium," Rich said.

But a revised forecast just completed indicates that the Medical School will suffer operating budget deficits in all but the first year.

Rich said the initial forecast was based on a three percent projected growth in faculty and staff annually, and an assumed 10 percent increase in faculty salaries.

"This rate of increase is considered necessary," Rich said, "because the salary structure in the School of Medicine is significantly behind that of the rest of the University, being at the 60th percentile for medical schools nationally, except in the basic science departments which are at approximately at the 75th percentile."

Rich said the Medical School revised forecast will not support the projections "we had planned to achieve."

Consequently, major reductions and significant reallocation of resources would be necessary to make it possible for the School to support its critical academic programs, he asserted. Similar steps will have to be taken in the Stanford University Hospital and Clinics and other Medical Center components.

Rich announced he was instituting effective immediately a program of Budget Review and Revision (BURR) for the purpose of evaluating budgets of all administrative and academic support services.

-more-

The first phase of BURR will apply to each division of the Medical Center administration, the Dean's Office, administrative services of the Medical School and Clinics, the administrative support activities of departments, and supporting academic programs, and selected hospital activities.

Plans call for evaluating the product and cost of these services, with a goal of achieving a 10 to 25 percent savings in net costs of operation, either by reduction of expenses or increased income or both.

A method for evaluating academic programs will be developed this winter in consultation with departmental chairmen and faculty, he said.

The School of Medicine is self-funded and receives its budget based on a general funds ceiling formula. The budget consists of gifts, Medical School endowment income, and funds received under the ceiling formula. This includes tuition income, and part of the overhead on grants and contracts awarded to the medical faculty.

The operating budget of the Medical School for fiscal 1974/75 comprises $10.3 million of a total budget of $36 million. The operating budget consists of $3.5 million from gifts and endowment, $5.1 million from tuition and overhead, and $1.7 million from clinical earnings and other sources. The remaining, $25.7 million consists of restricted funds--federal research grants and contracts, and nongovernmental grants.

The School uses the operating budget to support its own administrative services, including departmental administrations, a portion of the cost of salaries of faculty and staff, educational and research support services such as the library, office of student affairs, learning center and animal facilities, custodial and maintenance services, and utilities.

The revised forecast for the Medical School, Rich explained, takes into account the combined effects of continuing inflation and depression and projected reductions in federal support. It also assumes that present economic conditions will continue for several years and then gradually abate.

Rich stressed the analysis of the Medical School's financial situation is as realistic as one can make it. "Improvement or further deterioration of the economy, wage and price controls, or altered federal policies having to do with biomedical research could change the situation one way or another," he said.

STANFORD--A special diet has been found to be effective in managing severe intestinal complications that result from radiation treatment in children with cancer.

The new work in radiation enteritis (inflammation of the intestine) was done by Dr. Sarah Donaldson, assistant professor of radiology at Stanford University Medical School, while she was a visiting fellow at the Institut Gustave-Roussy in Villejuif, France. She recently described the work at a meeting of the American Society of Therapeutic Radiologists.

Donaldson and her colleagues studied 44 children in France who had received whole abdominal irradiation as part of the management of their malignant disease. It was determined that subsequent inflammation of the intestines and bowel obstruction in these children was caused by the radiation, not by recurrence of the tumors.

The problem may be life-threatening, even though the cancer has been arrested. According to Donaldson, "no specific dietary therapy has been developed for this condition in children."

The diet consists of a blended mixture of substances that can be taken through a tube if the patient is too sick to eat or drink it. It is free of gluten (the protein of wheat and other grains), free of protein obtained from cow's milk and lactose, low in fat, and low in residue.

Donaldson calls it a "diet by omission," since it was developed by eliminating all the food items that affected the enteritis.

"Our work under the microscope gave us the clues," she says. "We made it free of fat and milk products, since we saw that the damaged bowel couldn't absorb milk. And we made it low residue to avoid further obstruction."

Donaldson describes a "dramatic reversal in the children's clinical status that began with the initiation of the diet."

Followup for the 14 longterm survivors ranged between 19 months and 7 years. There were no deaths attributed to radiation enteritis. Of those surviving, none have shown evidence of recurrent intestinal obstruction.

Roughage, gluten, milk, and fat were gradually added to the children's diets following improvement in their X-rays and small bowel biopsies. The diet, continued for 12 to 24 months in some cases, was gradually replaced to a normal diet which was well-tolerated.

The paper is the first description of the syndrome of intestinal injury following whole abdominal radiation in childhood. Dr. Donaldson points out that as the survival rate of children with these tumors increases, such complications of treatment become more apparent.

This is also the first time a specific dietary therapy has been published as the major form of treatment for radiation enteritis in children.

Work is now underway at the Institut Gustave-Roussy to determine if use of the diet during the period of radiation treatments would avoid later intestinal complications.

The diet is not yet in use at Stanford, but is under study.

The work was supported in part by grants from the Anna Fuller Fund, the National Cancer Institute, and the National Institutes of Health.

STANFORD — Dedication ceremonies will be held Friday, Jan. 10, for the Stanford Hemodialysis Center building at Stanford University Medical Center.

An open house for the new, one-story facility is scheduled from 3 to 5 p.m. with a dedication ceremony at 4 p.m.

The new SHC will replace the current overcrowded renal dialysis unit in the main Stanford Hospital complex. The new SHC will be able to accommodate seven patients at a time.

Dr. Clayton Rich, dean of Stanford University Medical School, will head a list of speakers at the dedication ceremony. Also speaking will be Dr. Daniel D. Federman, chairman of the Department of Medicine at Stanford Medical School; Dr. John Phillip Pennell, assistant professor of medicine (nephrology) and director of the SHC; and Paul Hofmann, director of Stanford Hospital. Master of ceremonies will be Dr. Rex L. Jamison, associate professor of medicine (nephrology) and co-head of the Division of Nephrology at Stanford Hospital.

Dr. Roy H. Maffly is the other co-head of the division at Veterans Administration Hospital in Palo Alto.

Hemodialysis was first performed at Stanford Hospital in 1965 after the hospital's auxiliary purchased a twin-coil artificial kidney for the Division of Urology. Hemodialysis was confined to the treatment of acute renal failure until early in 1968. Then the first patient was treated after his kidney which was transplanted from a living relative failed.

In July 1971 the Division of Nephrology was established by the Department of Medicine at Stanford, and the following year a master plan for hemodialysis at Stanford was drawn up.

The Stanford Hemodialysis Center treats patients with acute kidney failure, or those with chronic kidney failure who cannot dialyze themselves at home.

An important part of the SHC program is to train patients to dialyze and care for themselves at home, if possible.

In addition, the SHC acts as a "back up" support for four satellite hemodialysis units whose patients are admitted through the Stanford Dialysis-Transplant Committee. The satellite units are Monterey County General Hospital in Salinas, Queen of the Valley Hospital in Napa, Limited-Care Facility in San Jose, and Washington Hospital Dialysis Unit in Fremont.

Furthermore, SHC serves in the education of nurses, medical students, medical residents, and nephrology fellows. Also included in this category is research on special problems among dialysis patients.

Since January 1973, over 100 patients have been admitted to the unit for chronic hemodialysis, or home training. Approximately 350 dialysis "runs" (four to eight hours in duration) are performed each month at SHC.

STANFORD--An important laboratory advance, which may aid scientists in the study of human malignant lymphomas, was reported Tuesday (Jan. 7, 1975) by researchers at Stanford University School of Medicine.

With new techniques, the researchers have grown tumor cells from lymphoma patients in the laboratory. Except for Burkitt's lymphoma, a cancer found in African children, human lymphoma cells have not been grown successfully in culture.

Lymphomas are cancers of the lymph glands. The tumor cells grown at Stanford came from three patients with histiocytic lymphomas, one of the most malignant cancers of the lymphoma group.

The researchers, Alan L. Epstein and Dr. Henry S. Kaplan, said the cells will provide an important new source for laboratory investigations. They will pave the way for studies of drugs for chemical control of the disease, radiation treatment, and improved methods of diagnosis.

In addition, the cells can be used in a search for cancer-inducing viruses and in immunotherapy research, finding ways for stimulating natural body immunity against cancer.

The establishment of cell cultures from human tumor biopsy specimens has been difficult, the researchers noted. This is because dividing tumor cells require a critical combination of nutrients, growth factors, and environmental conditions for their continued sustenance outside the human body.

Epstein and Kaplan said their success was due to development of new cell culture methods that enabled the rapid testing of a large number of factors.

Moreover, by dividing the tumor cells of the patients into small samples and storing them at low temperatures, they were able to test each biopsy specimen repeatedly until the growth requirements of each individual tumor were uncovered.

The medical researchers said the establishment of these human malignant cells in culture is of particular note because they are free of the Epstein-Barr virus.

-more-

This herpes-like virus, which is associated with infectious mononucleosis and Burkitt's lymphoma, has been found to pass onto normal white cells the ability of continuous growth in the laboratory.

The researchers said that establishing a lymphoma cell line uncontaminated by Epstein-Barr virus has been a major challenge because the virus is present in many persons for most of their lives, including lymphoma patients.

Reporting their work in the December issue of Cancer, the journal of the American Cancer Society, Epstein and Kaplan said the cultured cells were strikingly similar to the patients' tumors from which they were taken.

"The malignant cells had the same chromosomal abnormalities and were capable of widespread growth when inoculated into the brains of "nude mice," they reported.

These laboratory mice are used because they lack a thymus gland and therefore do not have a cellular immunity to destroy the implanted cells. It is well accepted that when such transplanted cells "take" and proliferate, they are malignant, the researchers explained.

The cells were flown to Children's Hospital in Philadelphia where Drs. Werner and Gertrude Henle did the Epstein-Barr virus studies and confirmed its absence.

Epstein is a medical and graduate student at Stanford supported by the Medical Scientist Training Program of the National Institutes of Health. Dr. Kaplan is the Maureen Lyles D'Ambrogio professor of radiology and cancer research pioneer. Their work was supported by a contract from the National Cancer Institute, a grant from the John A. Hartford Foundation of New York, and by gifts to the Joseph Edward Luetje Lymphoma Research Fund at Stanford.

STANFORD--A search for life on Mars will begin this year, but Stanford scientists say they will be looking for microorganisms, not current civilizations.

"We have no reason to think that there are people like us on Mars now . . . The search for intelligent life elsewhere in the universe is another ballgame," says Dr. Elliott Levinthal, director of the Instrumentation Research Laboratory at Stanford University Medical School, and member of the team of scientists nationwide preparing to soft-land scientific instruments on Mars.

Since Dr. Joshua Lederberg, chairman of the Stanford Department of Genetics, coined the word "exobiology" more than a decade ago to denote the study of life other than on earth, the School has been actively involved in Mars research. Some of that work has led to extensive applications in medicine here on earth, according to an article in the current issue of Stanford M.D., publication of the Stanford Medical Alumni Association.

The scientists were involved with the Mariner 9 mission of 1972, the satellite which mapped more than 85 percent of the surface of Mars.

They are now involved in the camera system and life-detection experiments to be carried out on the planet in the Viking mission. Launch is planned for summer, 1975 and landing by mid-1976.

The National Aeronautics and Space Administration mission calls for soft-landing two automated science payloads on Mars, with the objective of obtaining data about the possibility of life on the planet. Instruments will examine the surface for microorganisms, for organic chemistry, minerology, quakes, magnetic dust, and gases.

Dr. Lederberg is one of seven eminent scientists on the mission's biology team, which has devised tests for life by photosynthesis, metabolism, and growth.

Dr. Levinthal is one of seven members of the imagery team, which has devised a pair of stereoscopic cameras to scan the surface and skies at different resolutions and wavelengths.

Mariner 9 revealed huge rifts that suggest the planet's interior may be geologically alive. Photos showed volcanoes larger than any on earth, giant basins, and channels extending for hundreds of miles with small tributaries and high "walls" suggesting water erosion.

Winds were recorded exceeding 120 miles per hour, and there were planet-wide dust storms. Mars' atmosphere was shown to be composed primarily of carbon dioxide with small amounts of carbon monoxide, oxygen, and water.

Photos also revealed that the two satellites or moons of Mars are what they appear to be: dark, battered, entirely natural objects.

- more -

During the Viking mission, scientists will seek answers to such questions as whether the wandering channels are beds of ancient rivers, how much free water is available to possible living systems, and how thick the polar caps might be.

The biology experiments devised at Stanford are based on the assumption that life on Mars would depend upon the same basic carbon chemistry that supports life on earth.

Most of both the universe we know and of life on earth is made of a few particular atoms: carbon, nitrogen, oxygen, hydrogen, helium, says Levinthal. Since the atoms most useful for life on earth are also in very high cosmic abundances, he feels that it is likely there could be enormous numbers of planets in our galaxy with the same behavior in their environment.

But the likelihood of finding living organisms on Mars during the Viking mission may not be great. "We know so little about the habitat of Mars that Martian bugs would be adapted to. With the limited weight we have for the biology package, and the limited options, it is a big gamble," says Lederberg.

He notes that there is no single, unambiguous "life detector." Tests based on what constitutes life on earth may not hold true for life on another planet.

As a result of technology learned from the NASA missions, Stanford has designed programs which are now becoming increasingly important in medical research.

A particularly outstanding example is the first shared national computer facility for medical research, known as SUMEX. Its purpose is to employ the computer to reach decisions and solve medical research problems by symbolic analysis.

Other instruments are being used in analyzing unknown organic compounds, or determining molecular structure, with applications in treating infectious diseases, for example.

Another instrument which came from initial NASA work is the cell separator, now produced commercially. Developed by Dr. Leonard Herzenberg of the Genetics Department, it is aiding the study of the body's immune system, helping determine the chemical and biological characteristics of different cells. This could lead to possible prevention of organ transplant rejection, and more effective treatment of diseases such as leukemia and hemophilia.

FOR IMMEDIATE RELEASE
STANFORD —

A new public lecture series on recent developments in diagnosing and treating skin diseases will begin Thursday, March 6, at Stanford.

The five weekly lectures, by members of the School of Medicine's Department of Dermatology, will focus on a variety of topics. They include venereal disease, acne, skin cancer, and psoriasis.

These lectures are free of charge.

A talk on "New Venereal Diseases" will open the series. It will be presented by Dr. Paul Jacobs, professor of clinical dermatology, at 8 p.m. in Cubberley Auditorium on campus.

"Changes in morality and patterns of sexual intercourse in the past 10 years have contributed to a marked increase in infectious skin diseases such as lice and herpes in the genital areas," Jacobs says. "It is important that people be aware of these problems and learn what they can do to help prevent them."

Director of the dermatology clinic, Jacobs is a 1953 graduate of the Stritch School of Medicine at Loyola University.

The lectures in dermatology are part of the Medical School's Progress in Medicine series. Initiated in 1965, the lectures are offered to the community as a public service, according to Dean Clayton Rich.

The other four dermatology lectures, scheduled for Thursdays in Cubberley Auditorium at 8 p.m., are as follows:

March 13: "From Diaper Rash to Acne—Childhood and Adolescent Skin Problems," by Dr. Alvin Jacobs. Senior attending physician and clinical professor of dermatology and pediatrics, Jacobs has helped pioneer the specialty of pediatric dermatology. The growth of the specialty in recent years has led to more systematic study and increased knowledge of skin disease in children, from newborns to teen agers. Jacobs received his M.D. from Johns Hopkins University in 1937.

March 20: "California Skin Problems—Sunburn, Wrinkles, and Poison Oak," by Dr. William Watson, attending physician and clinical assistant professor of dermatology. An active clinician, Watson has studied the skin problems of an outdoor society like California's, especially skin damage from the sun, as well as one of the state's most common skin diseases: poison oak. Watson graduated from the University of Michigan Medical School in 1964.

March 27: "Moles and Skin Cancer," by Dr. Norman Price, acting assistant professor of dermatology. He is interested in the relation of moles and cancer and, in particular, what triggers some pigmented skin lesions such as moles to turn malignant. Price earned his M.B. (cq) and Ch.B. from Trinity College in Ireland in 1970.

April 3: "Understanding and Treating Psoriasis," by Dr. Eugene Farber. Professor and chairman of dermatology, Farber is a noted authority on psoriasis. He is director of Stanford's Psoriasis Day Care Center, opened last year to provide daily hospital care on an outpatient basis for those with psoriasis. He and his colleagues have been instrumental in identifying how stress and other conditions influence psoriasis, and in developing more effective treatments for the skin condition. Farber is a 1943 graduate of the University of Buffalo Medical School.

FOR IMMEDIATE RELEASE
STANFORD –

J. Willis Hurst, M.D., eminent cardiologist and professor and chairman of the Department of Medicine at Emory University School of Medicine in Atlanta, Georgia, will present the 11th annual John Kent Lewis Memorial Lecture at Stanford University School of Medicine.

Dr. Hurst will discuss "Newer Syndromes in Cardiology" at 4:15 p.m. Monday, Feb. 24, in Room M106 of the Medical School. Physicians and other health professionals in the community are invited to attend.

Dr. Hurst served as president of the American Heart Association in 1971 and received the Gold Heart Award from that organization in 1974.

He became well-known as private physician and cardiologist of late President Lyndon Johnson.

Most recently his work has been in problem-oriented medical record keeping, examining how doctors make diagnoses, and logical approaches to patient data organization.

He received his undergraduate education at the University of Georgia at Athens, and his medical degree in 1941 from the Medical College of Georgia. He served as a cardiac fellow with Dr. Paul Dudley White at Massachusetts General Hospital, and in 1950 joined the faculty of Emory University School of Medicine in Atlanta, attaining his current position in 1957.

He has received many awards and honors, particularly for his teaching. He is also coauthor of *The Heart, Arteries and Veins,* a widely-used cardiology text.

The John Kent Lewis Lectures are presented annually in honor of the former chief of the Stanford Medical Service at San Francisco General Hospital. A 1922 graduate of Stanford Medical School and noted pioneer in heart research, Lewis died in 1961.

STANFORD –

Dr. John R. Vane, group research and development director of the Wellcome Foundation in England, will give the second annual Windsor Cutting Lecture at the Stanford School of Medicine on Wednesday, Feb. 19.

He will speak on "Prostaglandins and Aspirin-like Drugs" at 4:15 p.m. in Room M106 of the Medical School. The lecture is open to the medical community and the public.

Dr. Vane served as professor of experimental pharmacology at the University of London's Royal College of Surgeons before his appointment in 1973 to the Wellcome Research Laboratories. His most recent work involves prostaglandins and aspirin.

His degrees include the bachelor of science in chemistry from the University of Birmingham, bachelor of science in pharmacology from Oxford, and doctorates in philosophy and in science from Oxford.

After serving as assistant professor of pharmacology at Yale University in 1953-55, he returned to England to the Institute of Basic Medical Sciences at the Royal College of Surgeons.

He is a fellow of the Royal Society, joint editor of *Adrenergic Mechanisms* and *Prostaglandin Synthetase Inhibitors,* and has published numerous articles.

The Windsor Cutting Lectureship was established in 1973 by the faculty of the Department of Pharmacology and is supported by private contributions. It honors the memory of Dr. Windsor Cutting, professor and former chairman of the Department of Pharmacology, who also served as dean of the Stanford University School of Medicine (1953-57) and dean of the University of Hawaii Medical School (1963-71). Dr. Cutting died in 1972.

Given annually during the winter quarter, the lectures feature speakers prominent in the field of pharmacology.

FOR IMMEDIATE RELEASE

STANFORD –

Dr. Thomas A. Gonda has been appointed chairman of the department of psychiatry and behavioral sciences, and Dr. Robert H. Alway has been named medical director of the Stanford University Hospital and Clinics and associate dean for clinical affairs.

The appointments, effective immediately, were announced Tuesday, Feb. 11, by Dr. Clayton Rich, vice-president for medical affairs and dean of the Stanford University School of Medicine.

Gonda, 53, has had a distinguished career as a teacher, researcher, and administrator. He succeeds Dr. Albert J. Stunkard, who resigned from the chairmanship last November citing personal reasons.

A native of Vienna, Gonda obtained his A.B. (1942) and M.D. (1945) degrees from Stanford. He received further professional training at San Francisco Hospital and the Langley Porter Clinic.

He joined the Stanford faculty in 1954 and was promoted to professor of psychiatry in 1965. In 1968 he became an associate dean and director of Stanford University Hospital, and in 1973 he relinquished the position to assume responsibility of a newly created post of medical director.

Dr. Alway, 62, is professor of pediatrics and director of the Stanford pediatric clinic.

In his new position he will supervise patient care activities of the medical staff within the Hospital and Clinics as the focal point of interaction with community and faculty physicians, as well as interns, residents, and postdoctoral clinical fellows.

Dr. Alway also will coordinate the development of the quality assurance and professional standards review programs of the Hospital and Clinics.

As dean of the Stanford University School of Medicine from 1957 to 1964, Dr. Alway was responsible for the successful relocation of the School from San Francisco to the campus, and recruitment of faculty, which helped establish Stanford as a leader in medical education.

He holds degrees from the University of Minnesota, and received graduate training in pediatrics from the same institution.

STANFORD--You have just become a parent. However, your joy is subdued when you discover your child has been placed in the premature nursery.

The infant has respiratory distress syndrome, a common and serious respiratory ailment among many premature babies.

Weeks pass and your child is still in the special unit, still receiving specialized care which you would be unable to administer at home. You are becoming more depressed daily by the situation. Will the child ever be normal? Will he ever be able to come home?

These are common questions posed by parents with infants in Stanford University Hospital's East Nursery, where high-risk babies are cared for.

But now, under an innovative program initiated about nine months ago parents can be more optimistic because they actually participate in the care of the infants. They are involved in the everyday feeding, diapering and bathing chores. Furthermore, the parents are encouraged to hold their babies, talk to them and help them to "identify" with their own families.

This kind of interaction has been possible through innovations by nurses in a section of the East Nursery known as the "Romper Room" which allows them and parents more freedom in caring for the infants. Among these changes is a modification of the oxygen administration system which makes it easier for the babies to be handled.

The program is an outgrowth of a four-year study conducted by Dr. P. Herbert Leiderman, professor of psychiatry at Stanford. The researchers found that hospitals should do everything possible to encourage the interaction of mothers and their premature infants.

Those infants in the Romper Room need long-term specialized care and are transferred here from the more critical care unit across the hall.

The Romper Room generally houses between four and five infants, whose parents generally spend an average of several hours a day with their babies. The East Nursery itself has approximately 16 to 17 babies at any one time, accepting many infants that are referred by other area hospitals.

"This is a very difficult time for most of these parents," explained Stina Miller, clinical nursing coordinator in the nursery, "it's almost like a grief reaction in that they (the parents) were expecting a normal baby and it was a severe blow to them when it wasn't."

While the hard reality is being dealt with, the parents can begin physically caring for their children, she continued, but it is a formidable crisis for many parents.

"We try to support them as much as possible," Mrs. Miller noted, "we teach the parents the needs, which may be special, that the babies may have. We try to do the same kind of teaching for parents of infants that are discharged directly from the East Nursery."

-more-

222--East Nursery

For each shift there are generally two nurses in the Romper Room and between eight and 10 on duty in the main nursery. However, when the infants are considered "critical" the ratio is usually one nurse to one baby.

In addition to supplying the basic physical needs of the infant, nurses use play therapy and exercises with the infants which generally consist of toys designed to promote psycho-social, as well as muscular development. As a part of this program the nurses involve parents in the play and exercise periods.

"We have to make up for lost time because other babies already have started this kind of development," Mrs. Miller added. "To do this we encourage the parents to help stimulate this development. We even urge them to bring clothes and some play things."

One of the parents who spends time each day with her child in the Romper Room is Tani Wright of Quincy, Calif., whose boy Jared will be three months old Feb. 24. Jared suffers from bronchopulmonary dysplasia, a chronic lung disorder which some premature infants acquire after taking respiratory therapy for respiratory distress syndrome.

Because of his present condition, Jared is required to take in oxygen through tubing that is connected to a nose catheter. Despite Jared's complications, his mother is optimistic about his chances for a full recovery.

"The medical care here is really good," she said, "He also gets a social orientation that helps him to develop in that way. You know, he has a lot of aunts in here. All the nurses are his aunts."

She said she was "scared" when told her son would be taken to the Romper Room section. "I thought it meant he might not get well," she noted, "but they have all really helped him. Over here he gets a lot more love."

Once infants are discharged they are still checked regularly at a follow-up clinic. Depending on the child, the follow-up exams are usually completed within six months to a year.

FOR IMMEDIATE RELEASE

STANFORD –

Dr. David M. Kipnis, chairman of the department of internal medicine at Washington University School of Medicine, St. Louis, Mo., will speak Wednesday, Feb. 12, at Stanford School of Medicine as recipient of the fifth Louis and Dorothy Kovitz Visiting Professorship.

The lecture, "Regulation of Insulin Synthesis and Secretion," is open to physicians and other health professionals in the community. It will begin at 4 p.m. in Room M106 of the Medical School.

Dr. Kipnis' specialty is endocrinology and metabolism. He is noted for his work in diabetes, the control of metabolism, physiologic regulations of levels of blood sugar, and functions of the endocrine glands.

The Kovitz Visiting Professorship was established in 1969 by Dr. and Mrs. Louis Kovitz of Los Altos to bring outstanding lecturers to the Medical School.

A native of Baltimore, Md., Dr. Kipnis received the bachelor's and master's degrees from Johns Hopkins University and a medical degree from the University of Maryland School of Medicine in 1951.

He joined the Washington University School of Medicine in 1957, becoming professor of medicine in 1965. He is serving as director of the Washington University Lipid Research Clinic and is physician-in-chief at Barnes Hospital, in addition to his administrative duties.

Dr. Kipnis is a fellow of the American Academy of Arts and Sciences and a member of the Institute of Medicine of the National Academy of Sciences. His honors include the Lilly Award of the American Diabetes Association and the Ernst Oppenheimer Award of the Endocrine Society.

He is the author of numerous publications in the fields of endocrinology and metabolism and serves as editor-in-chief of *Diabetes.*

STANFORD –

Betty Harris, head nurse in Stanford University Hospital operating rooms died at Stanford Feb. 1 of an irreversible illness.

A native of Shelbyville, Tex., Mrs. Harris would have been 54 on March 1. She was graduated as an R.N. from Methodist Hospital in Houston, Tex.

For 24 years Mrs. Harris worked in the operating rooms of the hospital. When Palo Alto Hospital changed to Stanford ownership she became head nurse of schedule coordination, "a role she filled with competence, unique charm, and humor," said Ludmilla Davis, director of operating rooms. Mrs. Harris was an active member of the San Jose Chapter of the National Association of Operating Room Nurses.

Outside of her professional activities, Mrs. Harris was devoted to her family. She enjoyed gardening, sewing, and cooking.

Survivors include her husband Roy, a daughter Denise Michelle, her mother, brothers, and sisters in Texas, Arkansas, and Louisiana.

STANFORD--Dr. Eugene Farber, professor and chairman of the department of dermatology at Stanford School of Medicine, will discuss psoriasis in a free public lecture Thursday, April 3 at Stanford.

His talk, entitled "Understanding and Treating Psoriasis," will conclude the Medical School's progress in medicine lecture series on recent advances in the diagnosis and treatment of skin problems. It will begin at 8 p.m. in Cubberley Auditorium, in the School of Education on campus.

An international authority on psoriasis, Dr. Farber is also director of Stanford's psoriasis day care center, opened last year. Patients with psoriasis receive intensive care during the day at the center and return home each evening.

Psoriasis is a common skin disorder that causes itching, scaling and redness, and affects an estimated 6 million people in the United States alone. No permanent cure is known, but investigations by Dr. Farber and his colleagues of the basic mechanisms of skin cell growth and metabolism have helped pave the way for more effective treatment. Dr. Farber has also been studying the influence of environmental factors such as stress on psoriasis.

Dr. Farber is chairman of the Psoriasis Task Force, National Program for Dermatology and editor of the International Psoriasis Bulletin.

EDITORS: The following story is a feature about the Stanford University Medical Center's infant transport program.

STANFORD--Shortly after noon last December, Joaquin Livingston was born at Community Hospital of the Monterey Peninsula.

The tiny infant was premature and weighed only three pounds, seven ounces. He was in respiratory distress because his immature lungs could not take in enough air.

Before Joaquin was an hour old, pediatrician Dr. George Penn had arranged to have him transported to the intensive care nurseries of Stanford University Hospital.

By the time Joaquin was two hours old, a Stanford transport team, always on call for such emergencies, was in an ambulance speeding toward the Palo Alto airport to board a plane to Monterey.

During the half hour flight, the team members--Dr. Mary Ann Pass, housestaff pediatrician, Polly Sawian and Judy Hudson, both nurses--were busy planning what they would have to do when they reached Monterey.

The specially designed portable unit that would carry Joaquin had been carefully checked just before the team left Stanford and would be tested again in Monterey. Joaquin's life would depend on the proper functioning of all components: the oxygen ventilation system to help him breathe, the heat warmers to maintain a neutral temperature, the battery powered monitors for heart rate, fluid intake and blood pressure, and the stabilizing unit to prevent injury during sudden changes of speed or altitude.

In the third hour of Joaquin's life, the team arrived at his side. By this time, every breath the infant took cost him a lot of energy and he was in severe respiratory distress.

For the next two hours the team members worked with Monterey physicians and nurses to stabilize Joaquin and prepare him for his journery. They inserted a thin tube into the infant's umbilical artery to measure the concentration of oxygen in his blood. Another tube was passed into his trachea (windpipe) to provide a passage for supplemental oxygen. Then Dr. Pass began to pump pure oxygen into the underdeveloped, overworked lungs, by rhythmically squeezing a bag attached to the end of the tube. She or Miss Sawian would continue to breathe for Joaquin with the bag until a mechanical respirator took over back at Stanford.

- more -

By the time Joaquin was eight hours old, he was in the Stanford Hospital intensive care nurseries, breathing on a respirator and receiving antibiotics for suspected infection.

Over the next twelve days, doctors and nurses, especially trained to care for premature infants, watched over Joaquin around the clock. After eight days, Joaquin was able to breathe by himself, without the assistance of a respirator. In another four days he was well enough to return to the Monterey Hospital where his parents could visit him regularly.

At the age of one month he was strong enough to go home. Today he is in good health and as lively as any four-and-a-half-month old infant.

Joaquin was one of more than 200 infants brought to Stanford last year. Close to 300 are expected this year, according to Dr. Alvin Hackel, co-director of the infant and pediatric transport program.

Most of the children come from communities throughout northern California and Nevada, but infants have also been brought from other western states. Last month a Stanford team traveled to Hong Kong to bring back a seriously ill one-month-old.

Stanford is one of seven regional referral centers in northern California for critically ill infants and newborns, explains Hackel, senior attending physician and clinical associate professor of pediatrics and anesthesia. Each center has a program designed to meet the needs of the region it serves.

At Stanford, about half the infants come from more than 30 miles away. The trend is to use airplane rather than helicopter, notes Hackel, because airplanes are faster and safer. Several of the infants brought to Stanford are more than a month old.

The program, in existence since 1971, is a joint undertaking of the Medical School's Departments of Anesthesia and Pediatrics and the University's Department of Mechanical Engineering. Dr. Philip Sunshine, professor of pediatrics is the other co-director.

STANFORD--Dr. Ruth T. Gross has been appointed director of the Division of Ambulatory Pediatrics at Stanford School of Medicine and chief of pediatric clinics at Stanford.

Her appointment, effective immediately, was announced by Dr. Irving Schulman, professor and chairman of the Department of Pediatrics at Stanford Medical School.

Since 1973 she has served as professor of pediatrics and as associate dean for student affairs at Stanford Medical School. She succeeds Dr. Robert H. Alway, who is now medical director of Stanford Hospital and Clinics and associate dean for clinical affairs.

Dr. Gross has served as coordinator of clinical training in child health for medical students at Stanford and its affiliated hospitals. She has also served as an attending pediatrician in patient care on the wards and outpatient pediatric department. Under her supervision a youth clinic has been initiated which is designed for young people ages 12 through 18. The clinic provides counseling and health education, in addition to comprehensive health care.

Under her re-assignment, Dr. Gross will retain her student teaching duties in pediatrics.

From 1950 to 1959 she served on the pediatric faculty at Stanford, and served for two years as acting pediatric chairman of Stanford Medical School when it was located in San Francisco.

She is a graduate of Barnard College, Columbia University and received her medical degree from Columbia University College of Physicians and Surgeons in 1944.

She has held academic appointments at Radcliffe Infirmary, Oxford, England, and was a professor of pediatrics and co-director of the Division of Human Genetics at Albert Einstein College of Medicine when she joined Mount Zion Hospital in San Francisco in 1966 and served as chairman of the department of pediatrics there. She has also served as a clinical professor of pediatrics at the University of California in San Francisco.

STANFORD--A well-dressed, quiet-spoken physician stood near the entrance to Stanford University Medical Center on Thursday (March 27) holding a sign reading "Patients Pay Medical Malpractice Insurance. . ."

"What would you do with a $16,000 bill," he asked a passing doctor in white coat, who just shook his head. Frequently, passersby stopped to read, to wonder what was being "protested."

Richard C. Thompson, M.D., San Mateo anesthesiologist, had come not so much to protest but to "find out what people are thinking about the sudden astronomical malpractice bills.

"I received my bill for insurance coverage about three weeks ago--$15,808," Thompson said. "Translated into the cost per patient that I take care of--industrial accident cases and Medi-Cal patients--it's astronomical, and I can't in fairness pass that cost on to them," he says.

So he decided not to pay the bill, and consequently curtailed his practice at Mills Hospital, where he had been affiliated, since that hospital requires its physicians to carry insurance. Not without some consideration, he decided to take to the streets to inform the public about the malpractice problem.

He spent about an hour in front of Stanford Hospital, and plans to do the same at other Bay Area hospitals, on the streets of San Francisco, and in shopping centers. He also hopes to take his sign to Stockton and Sacramento.

Thompson, who received his M.D. degree from Stanford in 1944, says doctor's malpractice insurance rates have increased 500 percent and hospital insurance rates have doubled. "Write your legislator now," reads his sign.

He doesn't offer any specific solutions to the problem, but maintains, "There's no question the problem can be dealt with effectively by the Legislature. There has been sophisticated input to legislators--it just needs to be dealt with, not put on the back shelf."

He reasons that "lots of public support" will be needed to effect that action. "I just want to arouse the concern of the people who pay the bills," says Thompson. "I just want them to have sufficient concern to write their legislator, to let those who have the power to do something about the problem, do it, and promptly."

The high rate increases for individual physicians and for hospitals are nationwide, and have been attributed to extraordinary jury malpractice verdicts and out-of-court settlements. Insurance companies handling malpractice have in the past months called attention to the seriousness of the situation, and called for major changes in handling medical suits.

Upon questioning, Thompson feels one method might be to specify set legal fees for malpractice actions, or to establish impartial commissions instead of the present jury situation.

STANFORD--"Moles and Skin Cancer" will be discussed by Dr. Norman Price, acting assistant professor of dermatology, Thursday, March 27 at Stanford University.

The talk is the fourth in a series of lectures an recent advances in diagnosing and treating skin problems presented free of charge for the public by the School of Medicine. It will begin at 8 p.m. in Cubberley Auditorium on campus.

Price has done research on pigmented lesions such as moles and what triggers them to become malignant. He is also interested in the types of skin cancer often caused by exposure to the sun.

The speaker completed his medical education in 1970 at Dublin University in Ireland. He received further training as a dermatology resident at the University of Miami and at New York University, and joined the Medical School faculty in 1974.

STANFORD--Two gifts totalling $1.05 million to complete a portion of the new wing of Stanford University Hospital were announced Monday (March 17) by Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine.

A gift of $800,000 from the Donald E. Baxter Foundation of Los Angeles, and a gift of $250,000 from the Max C. Fleischmann Foundation of Reno, Nevada, will be used for construction of a new cardiology center to serve hospital and clinic patients.

The new facility, Dr. Rich said, will be named The Donald E. Baxter Cardiology Center and will be located on the second floor of the new $12.6 million hospital expansion now under construction.

"We particularly appreciate the generosity of the Baxter and Fleischmann foundations in providing this facility," Dr. Rich said, "which will greatly strengthen our ability to make progress in this critical aspect of medicine in the coming decade."

Stanford's cardiology division is nationally known for its work with antiarrhythmic drugs, development of monitoring devices to prevent sudden death, and use of engineering and computer technology in early detection, diagnosis and treatment of heart disease.

Heart patients come to Stanford from California and Nevada, and many other parts of the world, Dr. Rich added.

Dr. Donald C. Harrison, William G. Irwin professor and head of the Division of Cardiology, said the Center will permit a 30 percent increase in the number of patients now seen by Stanford cardiologists.

In addition, it will make it possible for the activities of the Department of Cardiovascular Surgery headed by Dr. Norman E. Shumway to be joined physically with those of cardiology.

The center will include a suite of four patient-evaluation laboratories and support facilities. One laboratory will specialize in nuclear medicine, and three others in ultrasound, blood-gas analysis, and x-ray diagnosis. -more-

They will be clustered around one viewing area and will be associated closely with a computer facility and a video-processing unit, which will service all four.

"The computer will enable us to judge and, if necessary, change what we are doing, without delay," said Dr. Harrison.

Computer analysis is presently applied to catheterization, a diagnostic procedure used to determine if the heart's function and blood output are normal and, if not, why not.

Before the computer was applied, it took four to six hours of a physician's time to make the necessary calculations," said Dr. Harrison. "The computer provides these data while catheterization is underway."

Dr. Harrison said Stanford's cardiology division has become one of the largest centers on the West Coast for training cardiologists and providing programs for investigative and clinical cardiology.

The Donald E. Baxter Foundation was established by Mrs. Delia B. Baxter in 1959 in honor of her late husband, Donald E. Baxter, a physician, scientist and engineer who pioneered in the commercial preparation of sterile and pyrogen-free solutions and associated medical equipment for intravenous therapy.

The foundation provides funds for scientific and educational purposes with primary emphasis on medical research. For many years it has provided funds for medical scholarships and research at Stanford, in addition to an endowed professorship in pharmacology.

The Max C. Fleischmann Foundation was established by the first chairman of the board of Standard Brands, Inc. (successor to the Fleischmann Company in 1929). Foundation funds have aided in the construction of a solar observatory on the Stanford campus and the Max C. Fleischmann Laboratories at the School of Medicine. The laboratories house medical student research projects, an audio-visual learning center, and other teaching and medical research programs of the School.

STANFORD--Common skin problems in California will be discussed at a free public lecture Thursday, March 20, by Dr. William Watson, attending physician and clinical assistant professor of dermatology at Stanford School of Medicine.

The lecture, entitled, "California Skin Problems: Sunburn, Wrinkles, and Poison Oak," will begin at 8 p.m. in Cubberley Auditorium on the Stanford campus. It is the third in the Medical School's series on developments in diagnosing and treating skin problems.

"The sun can be one of the most important factors in skin damage," says Watson. "The outdoor society of California is particularly susceptible to sun related problems such as wrinkles, aging, severe sunburn, and skin cancer."

Another prevalent problem in this area is poison oak. The next best remedy to avoiding contact with the plant is recognizing the itching skin lesions early and knowing what types of treatment are most helpful.

An active clinician, Watson helped coordinate the first statewide skin cancer detection program at the Stanislaus County Fair in Turlock in 1973. The screening has since become an annual event and will be conducted again at this summer's fair.

Watson is a 1964 alumnus of the University of Michigan Medical School. He took an internship at the Highland-Alameda County Hospital in Oakland and a residency in dermatology at Stanford. Before joining the Stanford faculty in 1972, he was on the faculty of Downstate Medical Center in New York.

STANFORD--Alain C. Enthoven, Marriner S. Eccles professor of public and private management at Stanford Graduate School of Business, has been appointed acting director of the Health Services Administration Program at Stanford, effective June 1.

The appointment was announced Wednesday (March 12) by Dr. Count D. Gibson, professor and chairman of Family, Community, and Preventive Medicine at Stanford School of Medicine and currently the acting director of the HSA program. Gibson will begin a one year sabbatical leave in June.

Enthoven, 44, a Stanford graduate, is a former Rhodes scholar and was a top aide in the Department of Defense during the Kennedy and Johnson administrations. He was the first recipient of the endowed chair at Stanford, established in 1973 by Marriner S. Eccles, former chairman of the Federal Reserve Board. In addition to serving as acting director of HSA, Enthoven will continue teaching all public management courses at Stanford Graduate School of Business.

Health Services Administration is a program designed to develop administrators and planners with interdisciplinary training for roles in public and private health organizations. Graduate students selected for the program are enrolled in medicine, engineering, business and humanities and sciences.

The program allows students to blend a variety of backgrounds and interests into health field careers and prepares them for work in the continually changing health care field.

The curriculum is centered in three general subject areas, including administration, quantitative techniques and health services systems. HSA graduates earn a master of science degree in health services administration from Stanford School of Medicine.

Before joining the Stanford faculty in 1973, Enthoven was president of Litton Medical Products, a subsidiary of Litton Industries. He was one of a group of civilian experts former secretary of Defense Robert McNamara summoned to the Pentagon from the Rand Corporation at the start of the Kennedy administration. He was given the President's Award for distinguished federal civilian service by Kennedy in 1963, and 1969 he was awarded the Defense Department's medal for outstanding public service.

Enthoven has written extensively on monetary theory, defense and economic spending and he was an economics instructor for one year at Massachusetts Institute of Technology. He received his B.A. in economics from Stanford in 1952, and A.B. in philosophy from Oxford and a Ph.D. in economics from MIT.

STANFORD--"From Diaper Rash to Acne: Childhood and Adolescent Skin Problems," is the topic of a lecture by Dr. Alvin Jacobs, clinical professor of dermatology and pediatrics, Thursday, March 13, at Stanford University.

The free public lecture is the second in a series on recent advances in dermatology presented by the School of Medicine. It will begin at 8 p.m. in Cubberley Auditorium.

In recent years, both dermatologists and pediatricians have devoted more attention to skin problems in children, points out Jacobs. The growth of the specialty in pediatric dermatology has led to increased knowledge of childhood skin diseases.

"There are common observations that can be made even in the newborn--the distribution of hair, peeling of skin, growth of fingernails, for example--that provide clues to the health status of the baby," Jacobs says.

One of the most pressing adolescent skin problems, he continues, is acne, which generally occurs at the beginning of puberty. "Contrary to popular belief, a lot can be done to control the problem and avoid permanent physical and emotional scarring effects."

Jacobs, also senior attending physician in dermatology and pediatrics, received his M.D. from Johns Hopkins University in 1937. He joined the full-time faculty of the Medical School in 1972 after retiring from private practice.

STANFORD--Bladder infections after sexual intercourse, a common and perplexing malady for many women, can now be prevented with a single dose of an antibiotic, a Stanford University Medical Center study shows.

Dr. Kenneth L. Vosti, professor of medicine, treated 14 patients with chronic or recurring urinary tract infections for one and a half to nine years.

Treatment consisted only of taking a single antibiotic pill after sexual intercourse.

The incidence of infections was reduced significantly when the patients received the treatment as compared to equal periods of time when they did not, Dr. Vosti reported.

His conclusions appear in an article in the current issue of the Journal of the American Medical Association.

Dr. Vosti said no serious side effects from use of the antibiotics were encountered.

In some women recurrence of infections can be related clearly to sexual intercourse, Dr. Vosti said, presumably because it provides a means of entry of bacteria from the urethra into the bladder.

These patients must also have other as yet unrecognized defects in bladder defenses against infection, he added, since previous medical reports have shown that when bacteria were introduced into the bladders of normal volunteers infection did not develop.

Infections in the patients studied ranged from the simple presence of bacteria in urine without any symptoms or patient discomfort to more acute forms of cystitis or bladder inflammation.

Dr. Vosti said some patients, as a result of frequent symptomatic infections will curtail sharply their sexual activity, leading frequently to marital tension.

Doctors have tried a variety of methods to cope with this problem. Often such patients are advised to wash the genital area and empty the bladder after intercourse.

"In general, these practices have not been successful either because they don't work or because patients find them inconvenient and fail to carry them out," Dr. Vosti said.

Instead these patients first receive antibiotic treatment after intercourse. In his study, he reported, many of these patients will be successfully treated by this simple regimen.

"If it fails to control recurrences, the patients may receive a single dose of antibiotic nightly, or more frequently if needed," he explained.

STANFORD--The Stanislaus County Fair in Turlock has become the site of California's first large-scale skin cancer detection program.

The annual screening project was begun in 1973 by the Stanford University Department of Dermatology. It is sponsored by the American Cancer Society and the National Program for Dermatology.

In a pilot screening booth at the 1973 fair, Stanford physicians examined the skin of 605 men and women. Of these, 149 had significant skin problems and all but 14 were referred to their personal physicians for further attention.

The 1973 study was reported in the February issue of The Western Journal of Medicine, the publication of the California Medical Society. Authors are Drs. William Watson, attending physician and clinical assistant professor of dermatology at Stanford, and E. Dorinda Loeffel, a former Stanford dermatologist now of Chicago.

A smaller detection program was conducted at the 1974 fair, but more comprehensive screening will be done again at this summer's fair, according to Watson. He explained that Californians who are in the sun frequently are particularly susceptible to malignant or premalignant skin lesions. Yet skin cancers can be recognized early and in most cases treated successfully through simple surgery or radiation therapy.

Turlock, located in California's hot and fertile San Joaquin Valley, has a population of farmers and ranchers at a high risk for developing skin cancer, the authors said.

In 1973, the 605 people seen ranged in age from three to 89 years old. Physicians examined only sun-exposed areas of the skin--face, neck, arms and upper chest--unless otherwise requested by an individual.

The 149 skin problems detected included 125 malignant and premalignant lesions. None of these were found in those under 25 years old.

In Turlock, where an estimated 50,000 people attend the county fair each year, a large population can be easily screened if fair-goers can be encouraged to visit the detection booth, the authors pointed out.

There is a second advantage to such a program. "Possibly the greatest long-term benefit could be cancer prevention through mass education concerning the hazards of prolonged sun exposure and the usefulness of sun-screens," they wrote.

They also noted that Caucasians with red or blonde hair, blue eyes and fair skin are more likely than others to develop skin cancer.

STANFORD--Stanford University scientists are investigating a clotting factor concentrate believed to offer hope for hemophiliacs who develop antibodies to treatment with the plasma protein their own bodies lack.

Hemophilia is a hereditary disease found almost exclusively in males. Victims of it lack one of the 10 proteins in blood plasma known to interact and cause coagulation.

Most hemophilia patients today can be treated successfully with infusions of the clotting protein known as antihemophilic globulin (AHG), also called Factor VIII. However, about 10 percent of these patients develop an antibody to the protein which complicates their therapy greatly.

The new lead, according to Dr. Judith Pool, professor of medicine, turned up almost accidentally. Someone treated an inhibitor patient with a batch of a different plasma protein concentrate rejected for general release because of "excess activity." He found that it worked.

The experimental concentrate is called activated prothrombin complex. Standard prothrombin complex is used to treat patients who have a congenital deficiency of Factor IX, another blood plasma protein. Since then other physicians have reported similar findings.

"Because of these findings we think the mechanism of action of this activated concentrate should be studied and understood," Dr. Pool said.

"We presume it contains activated intermediate products of the clotting process, enzymes, that short-circuit the inhibitor-antibody which these hemophilia patients have," she added.

As presently understood blood clotting is a sort of a cascade of enzymatic reactions which ends with the formation of fibrin, the clot itself. This part of the process has been studied most intensively and scientists know that it involves at least 10 enzymes, the biological regulators of most chemical reactions in cells. Each enzyme in the sequence activates the next until clotting takes place.

"We suspect the principal activated clotting factor in this material is thrombin, the last enzyme in the clotting chain," Dr. Pool said. "So we want to identify it and assay it.

Dr. Pool discussed the project with officials of the Hemophilia Foundation of Southern California at Beverly Hills because of the need for funds and equipment to pursue the work.

-more-

The foundation provided $10,000, Dr. Pool said. The money will be used in part to purchase a second Coag-a-Mate, an automated electronic machine which detects clot formation by the rate of opacity change in the plasma mixture. The new equipment will nearly double the number of assays a technician can turn out in a given day.

Dr. Pool also believes that specific assays can be developed to identify potential inhibitor patients. "We think it is extremely important to detect these boys before the antibody has appeared," she said.

One approach with these patients used at other centers, she noted, is to withhold treatment for minimal bleeding episodes and to save infusions of antihemophilic globulin for more serious episodes. This prevents increased antibody formation.

But it means more hemorrhaging, slower recovery, more crippling, Dr. Pool said. The approach at Stanford is to use small doses. These are usually effective because the antibody destroys Factor VIII slowly. Use of the experimental preparation is increasing, however, because it appears to be effective without stimulating more antibody formation.

"The foundation ordinarily does not support hemophilia research in Northern California," said Dr. Walter Platz, a foundation official. "But we decided to do so in the case of Dr. Pool because of the exciting prospect of her work and reputation in the field."

Dr. Pool discovered a way to separate Factor VIII from blood in 1964, in such a way that the rest of the blood in blood banks is still fully usable for ordinary transfusions.

Until that time, the boys were frequently infused with massive doses of blood which were rough on the patients' circulatory systems as well as expensive.

Now, when a boy suffers a bump that starts to bleed, he can give himself an infusion of the antihemophilic substance at home.

Dr. Pool is also studying the immunological characteristics of Factor VIII and of the antibody which might lead to an understanding of what is different about the 10 percent of the bleeders who develop the complication.

"Although it was formerly feared that inhibitor production was due to multiple transfusions with Factor VIII, it now seems more likely that the tendency to form the antibody is hereditary," she said.

EDITORS: The following story is a feature about the Stanford University Medical Center's infant transport program.

STANFORD--Shortly after noon last December, Joaquin Livingston was born at Community Hospital of the Monterey Peninsula.

The tiny infant was premature and weighed only three pounds, seven ounces. He was in respiratory distress because his immature lungs could not take in enough air.

Before Joaquin was an hour old, pediatrician Dr. George Penn had arranged to have him transported to the intensive care nurseries of Stanford University Hospital.

By the time Joaquin was two hours old, a Stanford transport team, always on call for such emergencies, was in an ambulance speeding toward the Palo Alto airport to board a plane to Monterey.

During the half hour flight, the team members--Dr. Mary Ann Pass, housestaff pediatrician, Polly Sawian and Judy Hudson, both nurses--were busy planning what they would have to do when they reached Monterey.

The specially designed portable unit that would carry Joaquin had been carefully checked just before the team left Stanford and would be tested again in Monterey. Joaquin's life would depend on the proper functioning of all components: the oxygen ventilation system to help him breathe, the heat warmers to maintain a neutral temperature, the battery powered monitors for heart rate, fluid intake and blood pressure, and the stabilizing unit to prevent injury during sudden changes of speed or altitude.

In the third hour of Joaquin's life, the team arrived at his side. By this time, every breath the infant took cost him a lot of energy and he was in severe respiratory distress.

For the next two hours the team members worked with Monterey physicians and nurses to stabilize Joaquin and prepare him for his journey. They inserted a thin tube into the infant's umbilical artery to measure the concentration of oxygen in his blood. Another tube was passed into his trachea (windpipe) to provide a passage for supplemental oxygen. Then Dr. Pass began to pump pure oxygen into the underdeveloped, overworked lungs, by rhythmically squeezing a bag attached to the end of the tube. She or Miss Sawian would continue to breathe for Joaquin with the bag until a mechanical respirator took over back at Stanford.

- more -

By the time Joaquin was eight hours old, he was in the Stanford Hospital intensive care nurseries, breathing on a respirator and receiving antibiotics for suspected infection.

Over the next twelve days, doctors and nurses, especially trained to care for premature infants, watched over Joaquin around the clock. After eight days, Joaquin was able to breathe by himself, without the assistance of a respirator. In another four days he was well enough to return to the Monterey Hospital where his parents could visit him regularly.

At the age of one month he was strong enough to go home. Today he is in good health and as lively as any four-and-a-half-month old infant.

Joaquin was one of more than 200 infants brought to Stanford last year. Close to 300 are expected this year, according to Dr. Alvin Hackel, co-director of the infant and pediatric transport program.

Most of the children come from communities throughout northern California and Nevada, but infants have also been brought from other western states. Last month a Stanford team traveled to Hong Kong to bring back a seriously ill one-month-old.

Stanford is one of seven regional referral centers in northern California for critically ill infants and newborns, explains Hackel, senior attending physician and clinical associate professor of pediatrics and anesthesia. Each center has a program designed to meet the needs of the region it serves.

At Stanford, about half the infants come from more than 30 miles away. The trend is to use airplane rather than helicopter, notes Hackel, because airplanes are faster and safer. Several of the infants brought to Stanford are more than a month old.

The program, in existence since 1971, is a joint undertaking of the Medical School's Departments of Anesthesia and Pediatrics and the University's Department of Mechanical Engineering. Dr. Philip Sunshine, professor of pediatrics is the other co-director.

FOR IMMEDIATE RELEASE
STANFORD –

Can you take the risk of having a child that is mentally or physically defective for genetic reasons?

Many couples who have had one defective child or suspect that they may in the future are turning to the Stanford Genetic Counseling Clinic for advice on this dilemma.

Formed last fall by Dr. Luigi Luzzatti, professor of pediatrics, and Dr. Howard Cann, associate professor of pediatrics and genetics, the clinic counsels up to four couples a week.

Dr. Cann, clinic director, explained the "neutralist" approach taken by the counselors.

"We supply information and the opportunity to discuss it and ask questions," he said. "It's up to the couple to make a decision—whether to have the child, an abortion, or whatever. Many people have difficulties accepting probability information, but we don't tell them what to do. We take a neutral stance."

"If a couple has a 25% chance of having a defective child, we try to put that in clear terms—a chance of one in four. We also say that there is a 75% chance their baby will be normal."

Physicians can now detect 20 to 30 genetic diseases before the child is born by a test called amniocentesis. A sample is taken of the amniotic fluid surrounding the fetus, which also contains fetal cells that have sloughed off.

Dr. Cann suggests that pregnant women over 35 consider undergoing amniocentesis to determine if their baby might have Down's Syndrome, or mongolism.

Statistics show that the normal risk for a 20-year-old mother is less than one chance in 1,000. For a woman of 45, the risks shoot up to one chance in 50 that her child will have Down's Syndrome.

This test can also determine the sex of a child when parents fear the possibility of a sex-linked inherited disease.

Cells from the fetal amniotic fluid can be "cultured" and grown so that the presence of any one of 20 rare biochemical enzyme deficiencies can be detected and possibly treated in the newborn infant.

The procedure is performed in the obstetrics clinic at the Medical Center.

Dr. Cann stressed the genetic counseling clinic's policy of preparing couples so that amniocentesis is decided upon with "eyes wide open."

"They must know why the test is being done," explained Cann. "They should understand what the risk of complication is. It's actually very low for this test—fewer than one amniocentesis in 200 will develop complications."

Should the result of the test indicate the child will be defective, many couples consider abortion.

"We in no way coerce couples to have an abortion," stressed Dr. Cann. "It's their own decision. We won't withhold amniocentesis if a couple says they won't undergo abortion."

The counseling sessions often last one to two hours, and both members of a couple are encouraged to attend.

(more) cr 4/22/75

Each couple is simultaneously counseled by one physician and Rose Grobstein, chief of pediatric social work.

This doctor-social worker team is helpful in situations where the parents of a defective child have defensive or guilt feelings they haven't come face-to-face with successfully.

A correct diagnosis is of the utmost importance in genetic counseling. Dr. Cann described the extensive search for medical verification and completion of a family tree to establish the risks involved for a couple interested in childbearing. This is important when inheritance of a disease is feared.

Often, Cann happily reports, "we are able to rule out the probability of genetic disease. We do a lot of work reassuring people."

The information a couple receives during a session is structured into two areas.

The counseling team first outlines the "recurrent risk," or probability that the couple will have a genetically defective child.

They also explain the "burden" that is to be expected. "Burden" describes what the life of the child and parents could be expected to be like—how long the child might live, how defective it would be, what the financial and emotional costs to the parents, child, and society would be.

People often ask about the effects of "street drugs" on genes.

According to Cann, "there is controversy over whether pot and some other street drugs cause deformed babies. We have no convincing evidence that they do."

He added, "We tend to be reassuring to women who have been exposed to X rays before conceiving or during pregnancy. The levels of exposure are almost always low. There is little evidence that the usual amounts of radiation used in diagnosis injures the fetus."

Dr. Cann criticized the temporary moratorium by the Department of Health, Education, and Welfare on fetal research.

He pointed out that though sickle-cell anemia, hemophilia, and other blood diseases are presently undetectable in the unborn child, a new, untested method utilizing a tiny telescope and a needle can extract blood from the fetus. This procedure may have potential in the detection of fetal blood diseases.

"But we're stuck because the moratorium prevents development of this method," he explained. "If we tested a fetus that a couple was considering aborting because of one of these possible diseases, only to find that it was healthy—couldn't that be considered saving the life of the fetus?"

The genetic counseling clinic at the Stanford University Medical Center is part of a popular surge of these clinics. It is one of 50 in California alone.

At least three universities award a degree for "genetic assistant" to those trained in human genetics, psychology, and social work counseling.

Dr. Cann was especially enthusiastic about such courses as "Medical Genetics" taught to medical students at Stanford Medical School.

"We want to teach doctors about genetic counseling. We hope that patients would get more out of a session with their family doctor than traveling 200 miles to see some guy they've never met at a university."

He predicted an increase in the number of genetic counseling clinics such as the one at Stanford.

"There is great interest in genetic disease now," he stated, "because so much more progress has been made toward understanding it."

STANFORD--Stanford University scientists have developed a prototype machine capable of constructing computer images of thin cross-sections of the body.

Called a computer tomographic X ray scanner, the instrument makes use of a fan of X-ray beams that travel through a patient and are detected by a Xenon multi-wire proportional counter. The computer then constructs the projections of the X rays into density distributions.

The result is a cross-sectional view that utilizes 32 colors to indicate different densities. Tumors and cancers show up as different densities than the soft tissue around them.

Dr. Douglas Boyd, one of the developers of the instrument, pointed out that the scanning time is only 10 seconds--short enough that a patient can hold his breath during the scan. This lessens the possibility of respiratory movement.

The Stanford physicists, radiologists, and electrical engineers who collaborated on the X ray scanner during the last four and a half years hope that it will be instrumental in the early diagnosis of cancer.

Dr. David Pistenma, radiologist, outlined the possible contributions of the scanner to medical technology.

"The scanner will improve detection of tumors. Most tumors today are not detectable until they reach a size of about 5-10mm. The scanner will hopefully pick up tumors that range from 1-2mm."

Dr. Pistenma added that improved diagnostic information would be of value to all physicians who rely on diagnostic radiology, including internists and orthopedic surgeons.

"The scanner can locate tumors in 3-D. This is important in planning treatment for cancer, because radiotherapists need to know where others organs in the body are in relation to the tumor itself. Say you have a tumor in the pancreas--the kidney, liver and spinal cord must be located because they are radiosensitive organs."

The X ray scanner's ability to pinpoint the exact location of tumors in soft tissue will aid therapy with the newly developed pion generator now undergoing testing. The generator explodes cancer cells by bombarding them with tiny subnuclear particles called "pimesons," and it is is expected to be used in patients in three to five years.

-more-

222--Computer X ray Scanner

Projected costs for the scanner are set at $50,000 to 75,000. Dr. Boyd is uncertain as to how much time will be needed for refinement of the scanner.

The X ray scanner is expected to be an improvement over the British-designed EMI Brain Scanner, which produces cross-sections of the brain only.

The EMI scanner uses X rays and a computer to construct black and white density patterns of the section. One of the difficulties with the EMI scanner is it's four and a half minute scan time, the length of which results in body movement in the patient.

Dr. Boyd explained the X ray scanner's advantages over the EMI instrument:

"Our machine looks at the entire body, not just the brain. We can do three-dimensional soft tissue cross-sections, measure a succession of slices, and pinpoint a soft tissue tumor--all within 10 seconds."

STANFORD--Stanford University Hospital and Clinics employees in five voting groups have rejected union representation for purposes of collective bargaining.

The elections were conducted by the National Labor Relations Board, and the votes were counted Saturday (April 12).

More than a 1,000 of the 1,200 eligible employees in four voting groups cast secret ballots Thursday, Friday, and Saturday. A total of 846 votes were against union representation.

The employees included: 1) allied health professionals, 2) service, technical, patient care, and plant clerical, 3) pharmacists, and 4) licensed vocational nurses.

"I am extremely pleased that about 85 percent of the eligible voters turned out to cast ballots and that the preference expressed was so overwhelmingly clear," said Paul Hofmann, director of the Hospital and Clinics.

The fifth group, interns and residents, received ballots by mail April 1 and returned them by Friday evening. They were voting on whether or not to be represented by the Stanford University Housestaff Association. It lost by 144 voting for the association and 150 against.

Of the other three labor organizations seeking to represent hospital and clinics employees, United Stanford Employees, Local 680 of the Service Employees International Union, AFL-CIO, received 98 votes; Stanford United Medical Technologists, 56 votes; and California Licensed Vocational Nurses Association, 16 votes.

A fifth union, the Stanford University Medical Center Engineering Association, seeking to organize maintenance employees withdrew from the election earlier.

According to John J. Schwartz, counsel for medical affairs, United Stanford Employees also attempted to withdraw on the eve of the election, but the National Labor Relations Board denied its request.

U.S.E. circulated leaflets Thursday urging its members to boycott the elections by casting blank ballots. Of the 20 void ballots, approximately 10 were blank, Schwartz said.

Jim Berk, U.S.E. president, Thursday was quoted in the Stanford Daily that the union had filed an unfair labor practices charge against the hospital with the San Francisco office of the NLRB.

Schwartz said "there is no merit to the charges."

STANFORD--Sammy King, wife of former West Helena resident Robert King is reported in good condition at Stanford University Hospital where she underwent a heart transplant operation last week.

The operation was performed Friday, April 4, by a team headed by Dr. Norman Shumway, chief of cardiovascular surgery. Mrs. King is the 84th patient to receive a new heart at Stanford in California.

She is the daughter-in-law of Mr. and Mrs. J.M. Mathis of West Helena. The King's son Robby, age two, is staying with King's sister Beth Smith, also of West Helena, while the couple are at Stanford.

The King's are from San Antonio, Texas, where he is a communications analyst with the U.S. Air Force.

STANFORD--The problems of the terminal cancer patient is the topic of a talk by Orville Kelly of Burlington, Iowa, Friday (April 11) at 12 noon in Room M104 of the Stanford University School of Medicine.

Kelly, a 44-year-old cancer patient, is founder of "Make Today Count," an organization with chapters all over the country. It is made up of cancer patients, their families, persons with other incurable diseases and community members.

Their purpose is to share the problems of learning to live with a disease and to try to cope with them, Kelly said.

Kelly, former editor of a weekly newspaper in Illinois, learned that he had cancer in 1973. It was diagnosed as a lymphocytic lymphoma.

After surgery, he said, one doctor gave him an estimate of his time left, three years at the most.

He experienced feelings of isolation. The doctors were treating him from a medical standpoint. A minister or two had discussed the hereafter with him. He had no one to talk to about his present problems.

Kelly's answer was the founding of "Make Today Count," he said.

His Stanford appearance is co-sponsored by the Medical Center's allied health council and the Department of Family, Community and Preventive Medicine.

It is open to the public. ###

STANFORD--Dr. Stanley Cohen, associate professor of medicine at Stanford University School of Medicine has been named a faculty scholar of the Josiah Macy, Jr. Foundation of New York for the 1975-76 academic year.

The award, made annually by the foundation to support research of medical and public health scientists on sabbatical leave, was announced recently by Dean Clayton Rich of the School of Medicine, and the Macy Foundation Board of Directors.

Cohen will spend part of his sabbatical year at the John Innes Institute in Norwich, England, where he will study the possible involvement of bacterial plasmids in antibiotic production by streptomyces, a soil bacteria. Plasmids are extrachromosomal elements associated with a variety of hereditary activities in bacteria.

Head of the Division of Clinical Pharmacology, Cohen is a 1960 graduate of the University of Pennsylvania School of Medicine. Before joining the Stanford faculty in 1968, he was at the Albert Einstein College of Medicine in New York. ###

STANFORD –

Dr. Helen M. Ranney, professor and chairman of the Department of Medicine at UC-San Diego School of Medicine, will speak as second Katharine McCormick Distinguished Lecturer at Stanford University School of Medicine on Thursday, April 10.

A noted hematologist, Dr. Ranney will discuss "The Sickle Polymer" at 4 p.m. in Room M106. The lecture is open to physicians and health professionals of the community.

Dr. Ranney has an international reputation for her work in molecular genetics and hematology. A native of New York, she received her A.B. from Barnard College, Columbia University, and her M.D. in 1947 from the College of Physicians and Surgeons, Columbia University.

She was appointed head of the Department of Medicine at UC-San Diego in 1973, having served as professor of medicine at State University of New York at Buffalo and at Albert Einstein College of Medicine.

She is president-elect of the Western Association of Physicians, and has served as president of the American Society of Hematology. In 1972 she received the Martin Luther King Jr. Medical Achievement Award for outstanding contributions in the field of Sickle Cell Anemia.

The McCormick Distinguished Lectureship, established to bring outstanding women physicians and scientists to the School of Medicine, honors the late Katharine D. McCormick who left a $5 million bequest to Stanford in 1969 particularly "for the encouragement and assistance of women in medicine."

The Professional Women of Stanford Medical School invite those attending to a reception in the courtyard immediately following the lecture.

STANFORD--Stanford University School of Medicine has received a $500,000 gift from Johnson & Johnson to establish an endowed faculty chair in the Department of Surgery at Stanford.

The gift was announced Wednesday (May 27) by Richard B. Sellars, chairman of the Board of Directors of Johnson & Johnson in New Brunswick, New Jersey, and Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine.

The chair will be known as the "Johnson & Johnson Chair in Surgery" and will be held by a faculty member in that department. The holder of the new chair will be named in the near future, Dr. Rich said.

The Johnson & Johnson grant is one of several awarded by the diversified health care firm to medical schools to help improve the quality of patient care, reduce hospital costs and develop a high level of medical proficiency and skill. Mr. Sellars commented that the urgent need for more trained physicians in today's overburdened health care system prompted the company's contributions.

In addition to the new chair of surgery at Stanford, Johnson & Johnson has endowed chairs of surgery at Harvard, Columbia, New York University, Cornell Medical College and the New Jersey College of Medicine and Dentistry.

Dr. Rich said the new chair will assist the Department of Surgery in adding to its distinguished faculty. The department has had a solid tradition of academic excellence, graduating surgeons who now head departments and units throughout the United States.

The department has worked vigorously to develop strong clinical services, aimed primarily at introducing medical students to the best and most advanced surgical treatment and care of patients, Dr. Rich said.

The university surgeons have also developed a strong community reciprocal relationship, an accomplishment he values highly.

Dr. Rich said more than 180 community practitioners contribute their skill, time and interest to surgical teaching programs.

EDITORS: Copies of The Stanford Magazine are available if not included with story.

STANFORD--A Stanford University psychiatrist says some 0.3 percent of the people in the United States--almost as many individuals as are schizophrenics--are incapacitated by fear and phobia.

"Among the common fears," says Dr. Stewart Agras, "fear of snakes, heights, storms, doctors, sickness, injury, and death lead the list."

But the commonly occurring fears and the less common phobias pose a fascinating research and treatment problem which is only gradually being solved, writes Agras in the current issue of The Stanford Magazine, published by the Stanford Alumni Association.

Phobias of adult life tend to be chronic, severely disabling and are difficult to treat by traditional psychotherapy, notes Agras. It is estimated that there some 635,000 phobics in this country.

But successful use of behavior modification techniques might be an approach to the problem. This approach, based on reward and punishment, has only begun to be explored in psychiatric treatment, Agras said.

"The technique," he explained, "simply boils down to the way in which the patient is induced to go out and actively confront the phobic situation."

Agras described the case of Jane, a patient treated successfully with behavior modification techniques.

Jane suffered from a condition called agoraphobia, also termed the "housebound housewife" syndrome, even though it affects almost as many men.

The patient was unable to leave home shortly after she married. Just a few yards away from her house, she would become terrified, imagining she might faint, choke, or even die if she did not return home at once.

Jane was first treated with psychotherapy and medication, but neither helped. Then, Dr. Agras and his colleagues tested a simple treatment approach, "the effect of a therapist's paying attention to and praising the patient's progress."

"We laid out a one-mile course from the hospital to downtown, marked at about 25-yard intervals so that the distance walked alone from the hospital could be measured," Agras said.

-more-

"The patient was asked to walk as far as she could without undue fear. If the patient walked each day further than before, she was praised enthusiastically. If not, the therapist was silent.

As Dr. Agras hoped to prove, the patient gained self-confidence and walked further. But when praise was withdrawn in later sessions, her phobia returned.

"This reversal of progress demonstrated that praise was responsible for the therapeutic effect," Agras said. "When praise was started again, the patient was very rapidly able to walk alone downtown."

Eventually the patient felt quite independent, and praise was withdrawn much more slowly until she completely recovered.

Fears start in childhood, said Agras. Parents and children have similar fear patterns, suggesting they are inherited or acquired by example.

The whole idea of being fearful makes sense, Agras explained, because it protects a species against danger. Fear leads to fast action and flight, and these were useful to primitive man.

Studies have revealed that girls are more fearful than boys, that socioeconomic level makes no difference, and that there is no relationship between a number of fears and problem behaviors such as bedwetting or nightmares, he said.

Phobias are presumably common fears which intensify rather than follow the normal course of gradual disappearance, Agras said. The reasons are not known. But perhaps environmental events such as fearful parents or accidental frightening incidents may help intensify fears into phobias.

"Once a phobia becomes intense," Agras said, "the phobic expends so much energy avoiding the feared situation that it ensures its tendency to persist."

Fear of doctors starts early in childhood, Agras said, "and is probably reinforced by the occasional painful visit."

FOR IMMEDIATE RELEASE

STANFORD –

If Canada's experience is any guide, the advent of national health insurance will have only a relatively modest impact on use of medical services in the U.S.

Rapidly rising costs will remain a persistent problem, and defects in the distribution and organization of health services will demand concerted corrective efforts.

These conclusions are reached in a new book, *National Health Insurance: Can We Learn from Canada* (304 pp., cloth $10.95, John Wiley & Sons), edited by Spyros Andreopoulos, information officer of the Stanford Medical Center. It includes six invited papers and discussion highlights on this topic from the Sun Valley Forum on National Health.

Canada's experience includes two major lessons for the U.S., Andreopoulos declares: "The main objective of a national health insurance program is not to control costs, but to remove barriers to health care.

"If doctors and health services are badly organized, national health insurance will only reveal the magnitude of the problem and lead to a determination to do something about it. . . . Perhaps without going through such an experience once, it is unrealistic to expect professionals, providers, and politicians to agree on methods and goals.

"Canada is now looking beyond the problem of organization of health services to find ways to a healthier country. In this respect, Canadians are perhaps 20 years ahead of the U.S."

The Canadian effort now is exploring three perspectives: 1) human biology, including diseases which are part of an individual's inheritance or genetic makeup; 2) environmental issues; and 3) lifestyle, personal habits which create self-imposed health risks, such as smoking.

"These are threats to health that an organized health system can do little more than serve as a catchnet for its victims," Andreopoulos notes.

Canada now ranks among the world leaders in several indices of health care, he notes. Compared with Australia, Denmark, Sweden, the United Kingdom, and the U.S., its hospital and medical insurance coverage is equalled only by Sweden and Britain; it leads in physicians per thousand population; and it is second only to Australia in nurses per thousand people.

But the Canadian system is not problem-free, he adds. Because they took no efforts to control the type, quantity, and quality of hospital services and made no attempt to determine the number and types of physicians which would be needed, "Canada today has too many specialists and not enough primary doctors. . . .

"The annual rate of cost escalation has been between 12 and 16%, which is far in excess of the economic growth of the country. . . .

"Canada now finds itself with an excess of acute care beds, coupled with a shortage of alternative treatment, such as convalescent and custodial care facilities.

(more)

"Medical services are not yet equally accessible to all segments of the population because doctors prefer to practice in cities, and it is difficult to attract them to rural or isolated locations."

For every new physician, the system now incurs about $50,000 annually for his services and costs, plus $100,000 for inpatient hospital care, laboratory, and special nursing work. "Consequently, some provinces now have considered curtailing the doctors' freedom to practice in any one province," he notes.

In a forward to the volume, Dr. Philip R. Lee, director of the health policy program at the UC-San Francisco School of Medicine, notes that "increasing the supply of physicians to improve their geographic distribution and to restrain cost increases through competition among fee-for-service physicians is likely to fail on both counts.

"After more than a decade of experience with detailed budgets and incentive reimbursement experiments for hospitals, Canadian officials have adopted a strategy to limit the future establishment of hospital beds as the best means of cost control. . . .

"Although different conclusions may be drawn from this book, it represents a milestone in the attempt to place the debate on national health insurance in the U.S. on a more rational basis."

Forum participants agreed on the following conclusions, among others:

1. Introduction of national health insurance in Canada. . .did not appreciably alter the nation's basic structure for provision of health care.

2. Removal of financial barriers to medical care improved equality of access and removed the fear of financial catastrophe caused by illness. . .the poor in Canada have been going to doctors earlier and more often.

3. The great majority of the Canadian public appears to have perceived neither a reduction nor an improvement in the quality of medical care [since national health insurance].

4. There is no evidence that national health insurance has impaired the physician-patient relationship.

5. Introduction of national health insurance reduced resistance to [such pressures as wage increases for unionized, non-physician health personnel, introduction of expensive new medical technology, and lack of effective incentives to control costs] and to that extent contributed to increases in aggregate costs.

6. Fixed fee schedules may have inhibited sharper escalation of physicians' incomes, but they have not led either to a leveling off of physicians' incomes or to a significant containment of total medical services expenditures.

7. Professional peer review of physicians' charges has worked satisfactorily to detect and control excessive [use] and billing and fraudulent or inappropriate claims, but has not been effective in containing the multiplication of units of care under the fee-for-service system.

STANFORD--From modest beginnings three years ago, the American Red Cross-Stanford University Blood Center is steadily developing into a major blood procurement-research facility.

The center, located near V.A. Hospital in Palo Alto, is now supplying approximately half of Stanford University Hospital's blood needs, or 16,000 units a year, according to Dr. Carl F. Grumet, medical director of the blood center and the hospital transfusion service, and clinical assistant professor of pathology.

The remainder of the hospital's blood is procured from Central California Red Cross in San Jose and from Peninsula Memorial Blood Bank in Burlingame.

However, prior to 1972 Peninsula supplied nearly all of the blood used at Stanford Hospital, including Hoover Pavilion, and at Children's Hospital at Stanford. Some blood was also drawn at the hospital transfusion service in the clinical lab.

"The whole idea (for the blood center) was to combine an efficient Red Cross blood procurement and blood donation service with Stanford Medical Center's research and technical expertise," Grumet explained. "It is our responsibility to not only provide the best current blood products available, but also to do the development, testing and application of new methods which are beyond the capability of community blood banks.

"The present arrangement with our blood center is far superior to the old system," he continued. "For example, one donor can give four units of platelets in a single session with a specialized machine we now use. Furthermore, we now have better technical distribution as well as a frozen blood depot where we can store rare blood types."

He noted that with expanded surgical programs and progress in the use of blood components in cancer and leukemia therapy, Stanford Hospital's blood requirements have increased significantly.

"For example, we now use more platelets in one week than we did during all of 1965," he added. "In addition, research is now being carried on in such areas as immunotherapy, coagulation and tissue typing."

When blood is needed a request is sent to the blood center which then ships it to the hospital transfusion service on the second floor. The hospital is then responsible for cross matching, dispensing and regulating the blood units.

Under the working arrangement, Grumet said, the hospital pays the blood center for its processing costs. The hospital, in turn, charges the same costs to the patients. The entire cost of the blood is therefore limited to the laboratory expenses incurred in processing, without needless replacement penalty fees.

- more -

22--Blood Center

Volunteers, technologists, administrators and some research personnel at the blood center are affiliated with Red Cross while physicians and other research staff members are on the university payroll. The volunteers, who number 120, put in between 1,700 and 1,800 hours a week.

Harold J. Horoho, blood center adminstrator, estimates it will take at least two years to "build up a good (blood) reserve." He said he hopes by that time the center will be able to handle 20,000 units of blood a year.

Meanwhile, Horoho is more concerned with keeping up with the monthly demand, which includes blood for those persons with the more rare blood types and for leukemia patients.

A major advance in meeting this need has been the Model 30 Blood Processor, which was placed into operation at the center late last year. The processor is able to separate plasma from platelets, which are needed by hemophiliacs

The machine, which is designed to provide "compatible platelets" to a blood recipient, collects blood in a plastic bowl that spins at 4,800 revolutions per minute This drives the lighter plasma to the top, and with the push of a button, the plasma flows into a plastic bag Once the blood turns opalescent another button is pushed and that flow is sent into a second plastic bag, containing the platelets.

Another button is then pushed sending the collected plasma back into the donor's body. For one pint of blood the platelet collection process takes approximately 14 minutes and single donors can safely give platelets from between six and eight pints of blood (per session)

Since platelets are replaced by the body rather quickly any healthy person is capable of donating platelets every other day if it were necessary, Grumet noted

The blood processor is also capable of separating white cells, which are needed when suppressive drugs given a leukemic patient kill off his own white cells.

Donated blood is actually broken down into four component parts at the center, including red cells cryoprecipitate, platelets and plasma. Hence, one donated pint can be used to treat four different patients.

Grumet noted that none of the donors are paid. They are strictly volunteer and explained that a "strikingly high incidence" of hepatitis is encountered with paid donors. "So we are clearly better off with volunteers," he said.

Horoho noted that less than three percent of the population actually donates blood on a regular basis and that a "high percentage" of these donors are repeaters.

"This can be difficult for all of us," he said "For instance, we have an extremely high need for type O, RH negative blood for the newborn nurseries It is a chronic shortage and we have to continually call persons we know who have this type of blood Recently we called 50 women with this type and only one showed up."

Horoho said most healthy people can donate every eight weeks and noted that most people later say their first donation was the hardest "About 90 percent of them tell us the pain was not nearly what they thought it would be."

Although the center frequently calls previous donors with rare blood types, many persons visit the center on their own or go specifically to donate for a family member or friend.

The center offers a variety of blood coverage plans for donors and their families, ranging from one year to lifetime coverage, depending on the amount donated Plans for blood coverage are also available to those persons unable to donate, but who are willing to give volunteer service to any Red Cross program instead.

STANFORD--A highly successful heart valve developed from a pig's heart is now being used in humans, according to heart surgeons at Stanford University Medical Center.

The valve has had no mechanical failures, and its use has resulted in a low incidence of thromboembolism, a major cause of death following valve replacement.

Dr. Edward Stinson, assistant professor of surgery, said that extensive clinical tests in animals at several centers in the United States preceded use of the valve in humans.

He said pig valves are now used widely in U.S. medical centers and in Europe for either mitral or aortic valve replacements or both, with excellent results.

A total of 200 patients received mitral valve replacement with pig valves at Stanford between 1971 and 1975. An additional 126 patients had aortic valve replacements, and 35 patients underwent replacement of both mitral and aortic valves.

So far pig valves have resulted in better than 95 percent survival rate for patients who had their heart valves replaced. Practically all of the patients enjoyed an improvement in the functioning of their hearts.

The mitral and aortic valves control the flow of blood in and out of the heart. When they become diseased, the heart becomes sluggish and the patient, unless the situation is corrected, eventually dies.

In a report in the Annals of Thoracic Surgery earlier this year, Dr. Stinson said the incidence of clots in the blood stream is far lower than that which is found when other mechanical valves are used.

The device consists of a preserved pig aortic valve mounted on a flexible polypropylene platform covered with Dacron.

Dr. Stinson and his co-authors, Drs. Randall B. Griepp and Norman E. Shumway have concluded that pig valves provide "a technically and functionally satisfactory valve substitute...."

Stinson said the advantages to the use of tissue valves from pigs include the elimination of the usually necessary anticoagulants and the low irritation factor in blood.

He also said there has been only one mechanical failure in patients who received pig valves at Stanford and there has been no tissue rejection.

The pig valves are preserved in a chemical fixative, glutaraldehyde, and are now available commercially for use by open heart surgery centers, he said. ###

STANFORD--The deficit for operating Stanford University Hospital's hemodialysis center was significantly reduced when federal officials increased payments to Medicare patients undergoing chronic and home training dialysis treatments, it was announced today (May 9).

According to Paul Gallagher, unit manager of the hemodialysis center, the Bureau of Health Insurance increased its payments by an average of $32 per treatment or dialysis, thereby reducing the gap between what Medicare will pay for patients with chronic renal disease and what their treatment costs Stanford.

Presently, treatments run about $220 per session with Medicare now covering about $177 of that cost.

Medicare's decision will reduce Stanford's total deficit for running the hemodialysis operation from about $200,000 to approximately $118,300, Gallagher said.

He said the government's decision to increase its allocations resulted only after Stanford had filed a request (called an exception) with Medicare. He said another exception request will be filed, probably within a month, because of continuing cost increases. The second exception would hopefully reduce the deficit further, Gallagher said, and perhaps eliminate it altogether.

Several years ago the federal government expanded its Medicare laws to grant full coverage for practically everyone with chronic renal disease, regardless of age.

Stanford's new, one-story hemodialysis center was opened in January at a cost of about $180,000. It is presently handling between 35 and 40 patients, who need a combined total of 5,000 treatments per year.

Stanford officials had expressed concern that the hemodialysis center might have to be closed if the huge deficit could not be reduced. However, Gallagher said he is encouraged by Medicare's action and said he is hopeful another exception will be approved by the government.

Dialysis treatments are necessary for persons with kidney failure. In some cases three treatments are required each week. The dialysis process involves purifying the blood of uremic toxins by machine with each session usually requiring six hours.

FOR IMMEDIATE RELEASE
STANFORD –

Stanford researchers have found that it is safe to place premature infants on plain or gently rocking waterbeds inside the incubator.

In fact, a recent study shows that infants placed on oscillating waterbeds had significantly fewer apneic spells, or temporary cessations of breathing, than did infants in standard incubators.

Results of more than three years of study with waterbeds in the Stanford Intensive Care Nurseries were presented by Dr. Anneliese F. Korner, adjunct professor, at a meeting sponsored by the Department of Psychiatry and Behavioral Sciences Wednesday, May 7, at the School of Medicine.

Studies were based on 10 years of research with infants and rat pups which highlighted the importance of movement stimulation for the developing infant.

Movement stimulation in the uterus is caused by the fetus' movements in the amniotic fluid and by his mother's movements. The researchers' aim is to facilitate the infant's maturation and development by using a waterbed to make up for such stimulation missed by the prematurely born infant.

It has been found by Dr. Korner and her collaborators that such movement stimulation is much more potent in bringing about behavioral and developmental changes than is touch and body contact, long considered the most important form of stimulation for very young infants.

Two kinds of waterbeds were developed at Stanford. One allows the baby to experience the rocking produced by his own movements. The other waterbed provides, in addition, gentle, irregular oscillations in the rhythm of maternal respirations.

The waterbeds are the same size as incubator mattresses, only deeper. A plastic tray contains the bag, which is filled with two gallons of warm water. The temperature is maintained by the incubator heating system.

A highly elastic membrane covers the unit. Oscillation is provided with the help of a respirator.

The units are adapted to all medical procedures commonly used in an intensive care nursery, such as I.V. or oxygen administration, and are designed for hospital use only, not for home use.

In their controlled study, the researchers found that premature infants placed on the gently oscillating waterbeds for seven days had pulse and respiration rates, temperature, weight changes, and oxygen need similar to those in ordinary incubators. There were no indications that the oscillating waterbed made the infants "seasick."

But significantly fewer apneas were found in the babies on the oscillating waterbeds than among babies in the control group.

By the sixth day after birth, the incidence of apnea decreased among the babies placed on the oscillating waterbed, whereas it continued to increase in the control group.

Infants participating in the study suffered mild respiratory distress and apnea, mild hypoglycemia and hypocalcemia. Infants with moderate or severe respiratory distress, and infants with congenital anomalies were not included in the study.

According to Dr. Korner, the studies indicate that it is safe to proceed with further research to assess not only the clinical, but also the developmental effects of this change in incubator environment.

Further studies at Stanford will also help determine whether, once an infant has severe apnea, placement on the oscillating waterbed will shorten the course of this disorder.

The non oscillating waterbed was also found clinically useful particularly in the care of infants recovering from abdominal surgery.

In addition, a study of the developmental effects of waterbed flotation on premature babies has begun in collaboration with the Department of Pediatrics at Kaiser-Permanente Medical Center, Santa Clara.

The Stanford work is supported by grants from the Grant Foundation, Inc., the National Institutes of Health, and the Boys Town Center for the Study of Youth Development at Stanford. –30– cr 5/7/75

EDITORS: Details about Dr. Moos' work follow asterisks.
FOR IMMEDIATE RELEASE
STANFORD –

Dr. Rudolf H. Moos, Stanford professor of psychiatry and behavioral sciences and director of the Stanford Social Ecology Laboratory, has been awarded the Hofheimer Prize by the American Psychiatric Association at its annual meeting in Anaheim Wednesday, May 7.

The prestigious prize is awarded annually for outstanding psychiatric research. Moos was honored for his book, *Evaluating Treatment Environments: A Social Ecological Approach,* which describes his work in the new field of social ecology, the study of human environments.

Moos, who received his Ph.D. in psychology from UC-Berkeley, has been at Stanford since 1962. He is director of Stanford's psychiatry research training program, and chief of psychiatric research at the Veterans Administration Hospital in Palo Alto, where the Social Ecology Laboratory is located.

This award brings to four the number of Stanford psychiatry faculty members who hold the Hofheimer Prize. Others are Dr. Albert Stunkard, who won it in 1960, Dr. Seymour Levine, 1961, and Dr. William C. Dement, 1964.

The APA award is named in memory of Lt. Lester N. Hofheimer who died in action in World War II.

* * *

Can classroom environment change students' attitudes or achievement? Do some work environments cause more absenteeism or health problems than others? Will a college student's choice of dorm affect his behavior?

Designing ways that individuals can answer these questions has been the concern of Stanford's Social Ecology Laboratory.

Dr. Moos' best known contribution to the field of social ecology has been a series of "social climate scales." These are designed to enable staff, patients, employees in a particular environment, such as a hospital setting, to understand their environment better, its effects, and how they might change it.

"There has never been a way of systematically describing the environments in which individuals function—their 'ecological niche.' Why is it that an individual student does well in one classroom, but has problems in another? Systematic descriptions of the social environments of the two classrooms may help answer this question," says Moos.

The series of questions in the scales deals, for example, with persons' involvement, the support they receive in the environment, spontaneity, clarity of the program, as well as how they conceive of an ideal environment.

The information can then be returned to the people to motivate them to try to change their environment.

"The scales," says Moos, "show that environments, like people, have unique personalities. Just as some individuals are usually experienced by their associates as warm and supportive, some social environments are felt to be supportive by their members. Some individuals are dominating; similarly some environments are extremely controlling."

(more) cr 5/7/75

Use of the scales, he says, "could enable the clinician, physician, or social worker to aid their clients in choosing environments or in improving them. The systematic measurement of social climates could become an important aspect of the work of the diagnostician."

Moos' initial work involved evaluating psychiatric treatment environments. From that work he found that a wide variety of different environments could be described using the same dimensions.

Scales have been developed not only to measure the environments of hospital-based and community-based psychiatric treatment programs, but also juvenile and adult correctional facilities, military companies, university student living groups, junior high and high school classrooms, industrial and work environments, and families.

Moos has found that "psychiatric wards that emphasized autonomy and personal problem orientation have patients who like the staff and feel they can develop their abilities and increase their self confidence."

In military companies, climate was related to total performance on tests at the end of basic training, and to the AWOL and sick call rate. Companies with excessive sick call lists, for example, were also those where men felt that the work was repetitious and boring and without opportunity for leadership.

Moos also hopes that his scales will enable people to have better information about an organization before they get into it.

College catalogs, for example, provide little or no information about the social atmosphere even though this may affect student satisfaction and development. And the social climates of different work groups, he says, may be as important for job morale as rates of pay and fringe benefits.

Moos is the author of *Evaluating Treatment Environments,* 1974; coeditor of *Issues in Social Ecology,* 1974, and *Health and the Social Environment,* 1974; and author of the soon to be published *Evaluating Correctional and Community Settings.*

Two other books are forthcoming: *Human Adaptation: Coping with Life Crises,* and *The Human Context: Environmental Determinants of Behavior,* in which he will review the impacts of architecture, weather, population density, noise and air pollution, among others.

Moos' work is supported by grants from the National Institute of Mental Health and from Veterans Administration Research Funds. In addition, he is now involved in a study of the effects of alcohol treatment programs, work supported by the National Institute on Alcohol Abuse and Alcoholism.

STANFORD –

Dr. John C. Hershey, assistant professor of management science in the Health Services Administration program at Stanford School of Medicine, has been named a Robert Wood Johnson Health Policy Fellow for 1975-76.

The HSA program is run jointly by the Medical School and Stanford Graduate School of Business.

The fellowship was established in 1973 by the Institute of Medicine, National Academy of Sciences, with a grant from the Robert Wood Johnson Foundation.

As one of six persons who will serve as Johnson Fellows during 1975-76, Hershey will work with members of Congress in health care-related legislation, policies, and programs. The fellowship is conducted in cooperation with the American Political Science Association.

STANFORD--Dr. Leonard Hayflick, professor of medical microbiology, has been named to the newly formed National Advisory Council on Aging of the National Institutes of Health.

His appointment was announced recently by Secretary of Health, Education and Welfare Casper Weinberger. According to Weinberger the Council will "advise, consult with and make recommendations to the Secretary on programs relating to the aged" and to the recently established National Institute on Aging.

Hayflick is one of 12 appointees, who include lay people as well as physicians and scientists.

A leading researcher on the biology of aging, Hayflick is noted for his discovery that normal human and animal cells have a finite lifespan. He found that the ability of cells outside the body to divide decreases with the age of the donor. Their "genetic program" is played out and the result is aging.

Hayflick received his Ph.D. in medical microbiology and chemistry from the University of Philadelphia in 1956. He has been honored by numerous universities and government organizations for his contributions to the understanding of the aging process.

STANFORD--Nominations are being accepted for members of the Stanford University faculty to serve as University Fellows in 1975-76.

All members of the Stanford community are eligible to nominate candidates and nominations should be sent before May 15, 1975, to University President Richard W. Lyman.

Nominees should be men and women whose future at Stanford appears bright and who have promise of not only becoming distinguished teachers and scholars but also academic statesmen willing to involve themselves in university-wide problems.

Of the six current fellows, three will continue in the program during the 1975-76 academic year. Three additional faculty members will be elected as fellows beginning in the fall. Those fellows remaining are Paul A. Brest, law; Alexander L. Fetter, physics; and Lee H. Yearley, religious studies.

The University Fellows program was initiated in 1969 as an effort to encourage faculty members to examine and work on concerns that would make contributions of a general nature to the university. The program is supported by a grant from the Ford Foundation.

In addition to the six fellows, the program also involves four or five officers of the academic administration. Each fellow is appointed for a two-year term, with options for longer or shorter terms not precluded.

Over the two year period each fellow will have a total of five months of salary to make possible released-time from departmental responsibilities or to use as a summer supplement.

Dr. William H. Northway Jr., associate professor of radiology (diagnostic) and pediatrics, is among the 15 faculty members who have served during the five years of the program.

STANFORD--Dr. David Baltimore, noted molecular biologist, will deliver the third annual Edwin W. Schultz Memorial Lecture Friday, May 9 at Stanford University School of Medicine.

He will discuss "Reverse Transcription," a process which converts the information in ribonucleic acid (RNA) to deoxyribonucleic acid (DNA). His talk will begin at 4:15 p.m. in Room M106 of the Medical School.

A member of the faculty at the Massachusetts Institute of Technology in Cambridge since 1968, Dr. Baltimore is professor of biology and American Cancer Society professor of microbiology.

His work involves fundamental discoveries in how nucleic acids duplicate themselves in animal and tumor viruses. He was a member of the National Academy of Sciences committee with Dr. Paul Berg of Stanford which called for a temporary suspension of certain research with DNA until potential hazards were evaluated.

Baltimore, a native of New York, received his Ph.D. in biology from the Rockefeller University in 1964. He served as research associate at the Salk Institute for Biological Studies in La Jolla before joining MIT.

Currently he is also consulting scientist in medicine at Children's Hospital Medical Center in Boston, and consulting scientist in pediatric oncology at the Children's Cancer Research Foundation, Boston.

He is editor of the Journal of Virology, and serves on the Cancer Special Program Advisory Committee of the National Institutes of Health.

The Schultz lectureship honors Dr. Edwin W. Schultz, who served as chairman of the Department of Bacteriology and Experimental Pathology (now Medical Microbiology) for 33 years. His pioneering studies of poliomyelitis are well known in the field of virology. He died in 1971 at the age of 83, and the memorial lectureship was established by his family and friends.

FOR IMMEDIATE RELEASE
STANFORD –

For some people the thought of getting a cast conjures up visions of heavy plaster of paris whipped up in buckets, slapped onto a broken extremity and taking hours to dry.

Nothing could actually be further from the truth. In fact, cast making has undergone changes in recent years, perhaps the most interesting being an orthopedic casting system known as Lightcast II.

This type of cast can often be applied within 15 minutes, is approximately three times lighter than the traditional cast but much stronger at the same time, can be immersed in water and is porous, allowing the air to get in. For John A. Walker and Wilhelm Schueler, orthopedic technicians at Stanford University Hospital, this cast making system has streamlined their operation. Under a doctor's supervision, Walker and Schueler apply about one-third of the casts needed in the hospital. Correspondingly equal numbers of casts are annually applied in hospital surgery, the emergency room and clinics.

Still, despite the obvious advantages of the lightcast method, plaster casts still outnumber lightcasts.

"Lightcast will probably never replace plaster," Walker explained, "still, we're applying more and more of them all the time."

Walker said that lightcast is actually a soft, flexible, resin-impregnated fiberglass. It is applied over a cloth padding known as a stockinet and shaped by a technician or physician, who often will wear rubber gloves to keep the resin off his hands. In most cases the resin is harmless and only those persons allergic to it are likely to get a skin reaction. (By contrast, plaster of paris is sealed in gauze pads which can be applied after being dipped in water.)

Once the fiberglass is formed it is placed inside a harmless Lightcast II Lamp for three minutes in order to cure it. The machine generates ultraviolet light and the cast is usually rubbed for the first 15 seconds once it has been placed in the machine in order to expedite the curing process.

Walker noted that traditional plaster casts may take from 24 to 72 hours, in some cases, to be fully set as opposed to the lightcast method which often can be completed in 15 minutes, depending on the body areas involved.

However, with so many different kinds of casts in demand, Walker noted that cast setting can be risky business. "With some traction cases you could easily cause nerve injury if the cast is improperly applied," he said, "and for that and other reasons we go through extensive training and always have a doctor present."

Walker himself has worked in the Stanford Hospital cast room for two years and Schueler for five. Previously, Walker had been a nursing assistant at Stanford for three-and-one-half years.

Both Walker and Schueler are often called upon to help administer a number of different kinds of casts, including those for the legs and arms, hip and body casts. The casts themselves may be worn for as little as six weeks and for as long as a year, in some cases. When it is time to remove the casts they are usually cut with an electric cast cutter and hand tools.

–30– cr 5/1/75

1. Resembling a wide piece of tape, Lightcast II can be easily applied to the extremity. Lightcast is soft in its uncured state and can be "molded" by hand.

2. The cast is cured by placing it in the Lightcast II Lamp, which generates ultraviolet light. Here John A. Walker, an orthopedic technician at Stanford Hospital, does some final rubbing of the cast worn by Frank Aguirre, a nursing assistant.

3. Once it is ready to come off, Lightcast can be removed with an electric saw. As its name implies, Lightcast is lighter than traditional plaster of paris, but is three times stronger.

STANFORD--Stanford University Hospital rates for rooms and services will increase an average 10 percent starting next Tuesday.

The rise in rates reflects raises in salaries of employees as well as the inflationary cost increases in food, medical supplies, and utilities, said Paul Hofmann, director of the hospital and clinics.

Hofmann said the replacement of the hospital's equipment and other capital requirements are also becoming increasingly important cost factors.

The hospital board of directors Thursday (June 26) voted to raise the daily room rates between $13.50 and $16.50.

The daily rates will be $117.50 for ward, $128 for semi-private room, and $144 for a private room.

Daily rates for patients utilizing services of the housestaff (interns and residents) are $12.50 higher. Medical need for housestaff services is determined by the patient's attending physician.

The board also approved new rates for acute care units. Daily room rates for intensive care would be boosted to $390 and intermediate intensive care to $284.

The hospital director said the increases would have been higher if the hospital had not achieved cost reductions of more than $3 million in the budget process.

Hofmann added that Stanford Hospital's financial picture has been complicated by reimbursement programs for patients covered by Medicare and Medi-Cal (about 25 percent of Stanford patients are Medicare and 15 percent are Medi-Cal).

Under maximum rates stipulated by these programs, the hospital is grouped with those in Santa Clara County and reimbursed at a rate of $96 per day, far below what it costs Stanford to provide the service.

Stanford, however, is a highly specialized regional center and should be grouped with hospitals in the San Francisco-Oakland metropolitan area paid $133 per day, Hofmann said.

Last January Stanford Hospital increased its room rates an average three percent to offset a 100 percent boost in malpractice insurance premiums.

STANFORD--Congressman Robert H. Mollohan (D-W. Va.) Friday (June 20) completed seven weeks of radiation therapy at Stanford University Medical Center for treatment of an early-stage malignancy of the prostate.

"Congressman Mollohan has responded well to the treatment, and we have every reason to be optimistic about his condition," said Dr. Malcolm A. Bagshaw, chairman of the Department of Radiology at Stanford.

Mollohan, 55, checked in at Stanford May 2 as an outpatient. The prostate malignancy had been discovered during a routine physical examination by a physician at U.S. Naval Medical Center in Bethesda, Md.

During his treatment the congressman lived in Palo Alto. He is expected to return to Washington, D.C. after a brief recuperation period.

FOR IMMEDIATE RELEASE

STANFORD –

Stanford University School of Medicine awarded 154 degrees during its annual commencement exercises Sunday, June 15.

The ceremonies also honored six faculty members. The graduating medical class, however, elected not to grant student awards this year.

Medical degrees were presented to 81 men and women. The school also awarded 22 Ph.D.'s, 39 master's, and 12 bachelor of science degrees.

Diplomas were presented during ceremonies at Grant Courtyard at Stanford School of Medicine following Stanford's 84th annual commencement rites at Frost Memorial Amphitheater.

Dr. Clayton Rich, vice-president for medical affairs and dean of the School, and Dr. Ruth T. Gross, professor of pediatrics, presented the diplomas.

The faculty address was given by Dr. Daniel Federman, professor and chairman of the Department of Medicine.

The Henry J. Kaiser Award for outstanding and innovative contributions to medical education was presented by Dean Rich to Dr. Joseph P. Kriss, professor of medicine and radiology and head of the Division of Nuclear Medicine.

Robert Bennett Clark, a member of the 1975 graduating class, presented the Henry J. Kaiser Awards for excellence in teaching to Drs. Mahendra Ranchod, acting assistant professor of pathology; Mark Perlroth, senior attending physician and clinical associate professor of medicine (cardiology); Bruce Tune, assistant professor of pediatrics; and Stanley L. Schrier, professor of medicine and head of the Division of Hematology.

Dr. Federman was awarded the Arthur L. Bloomfield Award for recognition of excellence in teaching clinical medicine. His award was presented by Brian Leslie Kotzin, a member of the 1975 graduating class.

A reception in the Dean's Courtyard for the graduates and their guests followed the convocation ceremony.

All but one of the medical graduates will receive additional clinical training in hospitals across the U.S. One student will undertake research work.

STANFORD--Stanford University School of Medicine has been awarded a federal grant totaling $956,200 over the next five years to expand its research programs in epilepsy, a brain disorder that affects an estimated four million Americans.

The award, from the National Institute of Neurological and Communicative Disorders and Stroke of the National Institutes of Health, was announced today (July 28) by Dr. Clayton Rich, vice president for medical affairs and dean of the medical school.

Dr. David Prince, professor and chairman of the Department of Neurology and head of the epilepsy program said that researchers will study the function, structure and chemistry of the brain to clarify the following questions:

--how do brain injuries lead to epilepsy?

--what are the effects of epilepsy on the immature brain and its development?

--how do the damaged "epileptic" nerve cells in the brain behave?

--what effect does abnormal nerve cell activity have on the rest of the brain?

The most common form of epilepsy--"focal" epilepsy--occurs when a particular area of the brain is damaged. Each seizure begins with the same phenomenon which depends on the site affected. Seizures may be limited, and involve, for example, only altered sensation or jerking in a limb, visual disturbances, or emotional states. They do not necessarily result in convulsions, Prince explained.

While one-half to two thirds of epileptic patients can be controlled with medication, the remainder suffer seizures which often interfere with a normal lifestyle.

Many patients experience their first epileptic episode during childhood. It may be that there is a critical period, perhaps at birth and during early development, when brain disturbances that occur will later produce epilepsy in the mature brain, Prince said.

Prince's group has been studying the behavior of animal brain cells by using microelectrodes that can record the electrical activity of individual nerve cells. "Abnormal nerve cells such as those involved in epilepsy fire many impulses in bursts, disturbing the normal patterns of signals which carry messages between different parts of the brain. We need to know what the basic abnormalities are which cause these cells to act this way," Prince explained.

Another important question is whether the disturbance in certain nerve cells has any long-term effects on the entire collection of brain cells. There is now some evidence that abnormal electrical discharges (characteristic of epilepsy) in a small area can influence other parts of the brain and may affect subsequent brain function. "If this is true," Prince noted, "we might want to treat epilepsy much more vigorously at an earlier stage to prevent potential problems in the mature brain."

Investigators working in the newly funded program with Prince include Drs. K.L. Chow, David Holtzman, John Peacock and Philip Schwartzkroin in the Department of Neurology and Lawrence Mathers in Anatomy.

STANFORD--Stanford University Hospital officials are holding emergency meetings this week to take steps needed to offset a $4.5 million deficit precipitated by new Medicare regulations from the Department of Health, Education, and Welfare in Washington.

The new regulations, which go into effect August 1, set ceilings on daily charges for routine services that hospitals can collect from Medicare. The restrictions apply also to Medi-Cal patients because Medicaid law stipulates that state programs will not pay hospitals more than Medicare rates.

About 40 percent of Stanford hospital's patients are Medicare and Medi-Cal beneficiaries.

The projected deficit in the coming year stems from inadequate reimbursement, according to Dr. Clayton Rich, vice-president for medical affairs and dean of the School of Medicine.

It now costs Stanford $139 per day to provide standard inpatient care, but under the new rules the hospital will get $97 per day.

For purposes of reimbursing hospitals for Medicare, HEW has divided the country into Standard Metropolitan Statistical Areas (SMSA). These have been classified into five groups based on per capita income. HEW presumes that the cost of operating any hospital is proportional to the income level of the SMSA in which the hospital is located.

Stanford hospital has been placed in the same SMSA as community hospitals in Santa Clara County.

"The nature of the SMSA boundaries is inappropriate and arbitrary," said Rich. "These boundaries are political (state and county) rather than economic."

Rich said the new classification fails to take into account that Stanford hospital, located only 700 yards from the San Mateo County line, has labor costs and operation more closely aligned with those in San Francisco than San Jose. The regulations also ignore Stanford's scope of services, patient mix, and intensity of care.

Similarly sized hospitals in San Mateo and San Francisco counties (a different SMSA), may be reimbursed up to $133 per day for routine care under the new HEW guidelines.

He said Stanford will seek from HEW a reclassification on the basis that its costs reflect those of hospitals in San Francisco and San Mateo counties.

"Some measure of hospital output complexity should be added to the classification scheme to provide more equitable treatment of the teaching and highly specialized institutions," Rich added.

-more-

The appeal to HEW, however, cannot be made until after the new regulations are in force. The appeal takes 45 days or longer and during this time, the hospital will be losing income at the rate of $10,700 per day.

Rich said he had ordered a temporary freeze on hospital capital expenditures, and other steps aimed at reducing costs. These include reductions in administration, data processing, support services, and some patient care areas.

"If these measures fail," Rich said, "the hospital may be forced to limit care for Medicare and Medi-Cal patients to remain in operation."

He also said the hospital might take legal action if the appeal fails.

"Unlike most teaching hospitals in California," Rich said, "we receive no state support and, unlike many community hospitals in the region, we are not supported by a tax district. There is no endowment or reserve. The hospital must operate on the basis of income it receives."

The Association of American Medical Colleges recently indicated that 40 percent of the nation's teaching hospitals were affected adversely by the new regulations.

AAMC also filed suit on the grounds that the regulations discriminated unfairly against the teaching hospitals.

A U.S. District Court, however, allowed implementation of the HEW regulations stating that "atypical educational costs for hospitals...can be better identified through the exceptions process..."

STANFORD--Stanford University School of Medicine has received a gift of $6,358 from the California Community Foundation of Los Angeles to study the relation of oxygen lack and other injuries at birth to certain brain disorders, it was announced recently.

Research will be conducted by Drs. David Prince and Philip Schwartzkroin in the Department of Neurology.

"We know that lack of oxygen in premature and newborn infants can have long-term effects on memory, movement or learning," Prince said. "But very little is known about the influence of such an insult on the function of individual nerve cells."

The investigators will examine the chronic effects of oxygen deficiency on development of electrical activity and connections in the brains of immature animals. Their work may provide new clues for understanding and treating disorders of brain function such as epilepsy or cerebral palsy.

###

STANFORD--Dr. Eugene Farber, professor and chairman of dermatology at Stanford University School of Medicine received the 1974 Mr. and Mrs. J.N. Taub International Memorial Award for Psoriasis Research, it was announced recently.

A noted expert on psoriasis, Farber is director of Stanford's psoriasis day care center. His studies of skin cell growth and the influence of environmental factors such as stress on psoriasis have helped pave the way for more effective treatment of the skin disorder.

Farber is also chairman of the National Program for Dermatology Task Force on Psoriasis and editor of the International Psoriasis Bulletin. He received his M.D. from the University of Buffalo in 1943.

The Taub award was established in 1957 by Carol and Henry J.N. Taub in honor of their grandparents Mr. and Mrs. J.N. Taub with the hope that the award would be an incentive to develop methods to alleviate psoriasis.

STANFORD--Stanford University School of Medicine has been awarded a two-year grant of $70,000 from The National Foundation-March of Dimes to investigate a new method of detecting genetic defects before birth, it was announced recently.

The principal investigator is Dr. Leonard Herzenberg, professor of genetics. Drs. Michael Iverson and James Schroeder will also work with him.

Some fetal white blood cells cross the placental barrier into the mother's blood throughout pregnancy, Herzenberg explained. The researchers are working out a technique to identify and separate these cells from the mother's cells so they can be tested for inherited defects.

Using maternal blood would be safer than the present technique of amniocentesis which involves sampling fluid directly from the uterus and entails some risk to the fetus. It could be used for routine screening of pregnant women.

The group will use a highly sensitive instrument Herzenberg's laboratory helped develop--the fluorescence-activated cell sorter (FACS)--which can isolate cells according to their surface composition.

All cells in the body are covered with antigens, chemical fingerprints unique to each individual. Fetal cells are also coated with antigens, half of them inherited from each parent. Fluorescent antibodies which adhere only to the antigens inherited from the father will distinguish fetal blood cells from those of the mother.

The FACS rapidly separates the labeled fetal cells from the mother's cells and sorts them in test tubes. These cells can be stimulated to grow in the laboratory and can be tested for chromosome defects, or other indications of genetic disorders.

The work is also being supported by the National Institute of General Medical Sciences of the National Institutes of Health.

STANFORD--Northern California's first woman paramedic graduate, one of 19 persons who completed training Friday (July 18) at Stanford University Hospital, doesn't regard herself as "special," but she does feel she has a responsibility to help people.

Penelope (Penny) Babienco, 25, of Saratoga and her male classmates have been recommended to the California Public Health Department for certification as emergency medical technicians, or paramedics.

It is the second class to complete the Stanford paramedics course, bringing the total to 43 persons who have graduated at Stanford. The first class graduated on Dec. 21, 1974.

"I have just seen too many people die on the way to hospitals," Miss Babienco noted while explaining her interest in the paramedic field. "Some of the shabbiest care has been given on the scene. Many times it is a case of life or death, and I feel paramedics can often make the difference so that patients will live."

The daughter of San Jose physician Dr. Allorie W. Babienco, she admits she was "crazy" about ambulances and emergency care before she was hired one year ago by the San Jose Ambulance Co. as an ambulance attendant. She will now become part of the company's second crew of working paramedics in the field. Six of the firm's first seven paramedics also graduated from the Stanford program.

The paramedics course, directed by Dr. Michael Eliastam, director of emergency services at Stanford Hospital, involves 200 hours of lecture and 300 hours of clinical and field work from Stanford physicians and nurses. Course instructors are registered nurses Charlene Souza and Toni Day.

Originally, Miss Babienco had intended to do volunteer work among the Navajo Indians in southern Utah after graduating from Pacific Union College in Angwin, California. ("I majored in piano performance which everyone always laughs about.") However, her plans fell through and she decided to investigate her interests in emergency care.

- more -

"Ambulance work keeps you in touch with reality and life," she said. "When you see a seven or a 10-year-old child die it does something to you, it really sobers you. I think that I now have a very healthy respect for life."

A part-time freelance writer, Miss Babienco does not consider herself a women's liberationist. "I feel I can retain my feminity and still work on the ambulance," she commented. "I do feel, however, that women's pay should be the same" (as the men).

Miss Babienco was the first full-time woman ambulance attendant to be hired in Santa Clara County, but she says she never gave it much thought. "Fact is, for a long time I didn't even know it."

The 19 graduates and their hometowns are:

San Jose: Jerry Dumas, Gary Skalko, Daniel Venosta, Robert Worsham, Bill Bazuik; Vallejo: Mark Berto, James Innes, Joe Gee; Bethel Island: Ted Alesna, Leroy Burnett; Berkeley: Michael Stettner; Campbell: Lance Valencia; Saratoga: Penelope Babienco; Palo Alto: Alex Brazelovich; Mountain View: Nick Marinaro; San Lorenzo: Dave Holland; Aptos: Phil Scofield; Dana Point: David Fleming; Atascadero: Glenn Graves.

STANFORD--Dr. Judith Graham Pool, 56, professor of medicine at Stanford University School of Medicine and noted hemophilia researcher, died Sunday (July 13) at Stanford University Hospital after an illness of several months.

Dr. Pool was recognized internationally for developing a simple method for extracting from normal blood the protein (called Factor VIII) needed by hemophilic patients.

Availability of the missing clotting factor has enabled hemophiliacs to treat themselves at home with injections, reducing both the length of hospitalization and treatment costs.

She was awarded the Murray Thelin Award of the National Hemophilia Foundation in 1968 for her work.

Recently, Dr. Pool had been investigating another concentrate which may offer hope to the small percentage of hemophilia patients who develop complications from the standard Factor VIII treatments.

Dr. Pool had also been active in promoting opportunities for women in medicine. She was the first co-president of the Association of Women in Medicine, formed in 1971, and the first chairwoman of the Professional Women of Stanford Medical School organized in 1970.

Professor Pool was born in New York City. She attended the University of Chicago, earning a bachelor's degree there in 1939 and her Ph. D. in physiology in 1946.

She later taught at Hobart College in New York State before joining the Stanford medical faculty in 1957.

Dr. Pool belonged to numerous professional organizations including the American Physiological Society, the American Heart Association's Council on Thrombosis, and the World Federation of Hemophilia. She once spent a year as a Fulbright Research Fellow in Norway, and also studied for a year ending in May, 1974 at the Oxford Hemophilia Center in England.

Dr. Pool lived on the Midpeninsula since 1949 except for a period spent in San Francisco. She had lived since in Menlo Park.

Survivors include her two sons, Jonathan Pool of Setauket, N.Y., and Jeremy Pool of Boston; her daughter, Loma Pool of Menlo Park; her mother, Nellie Graham of New York City; a sister, Ruth Stark of Roslyn, N.Y., and a brother, Walton Graham, of Roslyn Estates, N.Y.

STANFORD--A hearing aid inside the head is one of the latest ideas for producing better hearing currently being explored by Stanford researchers. The major hitch in the development of such a device seems to be the lack of a small, rechargeable battery for a power source.

Researchers are attempting to improve on the conventional "behind-the-ear"hearing aids by studying implantable prototypes.

One type of aid being developed involves a totally implanted device contained entirely within the head. The device itself utilizes the same principle as today's aids, by which electromagnetic waves are converted into sound waves.

The implantable device requires the placement of a tiny magnet on the ear drum or ear bones. A microphone and small amplifier connected to a coil transmit amplified electromagnetic waves to the magnet, causing it to move. The movement of the magnet vibrates the ear drum or bones, stimulating the inner ear to relay messages to the brain.

According to Dr. Richard Goode, ear, nose, and throat specialist at Stanford University Medical Center and a developer of the implantable device, the main problem is the lack of a long-term power source.

Dr. Goode felt that progress being made in the field of rechargeable batteries will help this stumbling block to the development of a totally implantable device.

"We need a good power source," he said. "A hearing aid inside the head would be on during waking hours. Today's batteries just aren't durable enough to supply power for more than a few weeks. You can't replace a battery surgically every two weeks--that's no improvement over today's conventional aids."

Heart pacemaker patients have encountered the same problem. Every two or three years, the patient with a pacemaker must undergo surgery to have a new battery installed.

- more -

Recently, Pacesetter Systems, Inc. developed a rechargeable battery for heart pacemakers that can be recharged inside the person.

"This rechargeable battery is presently too big for our purposes," said Goode. "I hope within a year or two someone will come out with a rechargeable battery about the size of a quarter, or smaller. That would be just right for our implantable devices.

Another type of device being tested is the "partially implantable" hearing aid. It contains a power source in the conventional ear mold supplying power to a series of coils implanted inside the ear. This partially implanted aid would, like the totally implantable device, provide improved sound quality to the wearer over present day conventional hearing aids.

Dr. Goode outlined the advantages of the implantable devices he and other physicians and engineers are testing over conventional aids.

"Some of the limitations of conventional hearing aids include low fidelity, feedback, the need for a tight-fitting ear mold, and the presence of an externally visible device."

"An implantable hearing aid has the theoretical potential to improve all of these deficiencies and hopefully add no major ones."

Dr. Goode explained that an implantable device would not be marketable until it was capable of functioning as well as or better than conventional aids do.

"It won't help if the implantable device does not reproduce sound as well as today's hearing aids do. Being invisible is no improvement to the hearing aid wearer unless sound quality is improved too."

"Invisible" hearing aids developed a few years ago were found to have limited usefulness. The amplification supplied by the hearing aid was barely able to offset the hearing loss incurred by the device blocking sound waves entering the ear canal. Feedback was also a problem.

Dr. Goode estimates that a patient-ready model of the implantable hearing device may appear on the market within five years.

###

The above story was prepared by Christa Battelle, a science writing intern in the News Bureau. Mailed 7/10/75. Photos 1) of Dr. Goode and 2) outside of ear and X-ray showing device available on request.

STANFORD--A Stanford University psychiatrist says Americans are killing each other twice as fast as they did 20 years ago, and predicts that as long as the economy remains in a slump the nation's murder boom will continue.

"We are experiencing a murder epidemic that is breaking all previous records," says Dr. Donald T. Lunde. "More Americans were murdered from 1970 through 1974 than were killed during the entire Vietnam war.

"In 1975, one of every 10,000 Americans will be murdered."

Lunde, assistant professor of law and psychiatry, makes this grim prediction in a new book, Murder and Madness (133 pages, paper, $3.55, The Portable Stanford, Stanford Alumni Association).

A forensic psychiatrist, Lunde studied dozens of violent criminal suspects and testified in their trials. Among them were two mass murderers, John Linley Frazier and Edmund Emil Kemper III.

Lunde says the most likely murderer is still a victim's relative. "Almost a third of all victims are related to their killers," he reports.

The two peak months for murder are July and December (summer vacation and Christmas), Lunde says. This is when most people are with those most likely to kill them--relatives, friends, and drinking companions. Few homicides occur during business hours. But on weekends the murder rate soars.

Authorities do not recognize that increasing material expectations combined with a depressed economy have something to do with the growing murder rate, Lunde reports. They think the answer lies in tougher criminal penalties, increased rehabilitation programs, and more money to beef up police forces.

"The trouble is, murderers are not a homogeneous group of 'bad guys'," Lunde concludes. "For the most part, they are husbands, wives, lovers, neighbors, friends, and acquaintances--persons who can no longer endure chronic frustration."

Lunde observes that during economic depressions in the past, murder rates went down and suicides went up. The opposite seems true today.

"This reversal," he explains, "may have come about because Americans no longer blame themselves for their material misfortunes.

"When traditional values and the Protestant ethic reigned in America, we took out our frustrations on ourselves. Many committed suicide during the Depression for instance."

Now Americans have moved away from self-reliance and expect society to provide them with certain material things, the psychiatrist believes. When it doesn't, people strike out at others.

- more -

Most murders in the United States are committed by young adults, predominantly males and in their twenties. Young people also have a greater tendency than adults to blame outside factors if something goes wrong, Lunde believes.

But felony murders are also surging, Lunde indicates, and one big reason for this is lack of gun control. In felony murders the killer, almost always a man, kills for money, sex, or drugs, or when he tries to escape.

"Two-thirds of all murders in the U.S. are committed with guns, 92 percent of these with handguns," Lunde reports. "Gun ownership is highest in the regions with the highest murder rates."

The United States leads the world in the death rate due to firearms, Lunde says.

"Unlike any other major country," he explains, "we have carried on a domestic 'mini arms race' for generations and now face some of the problems internally that we experience on an international scale in trying to curtail armaments.

"The arms race aspect of guns proliferation applies to those who buy guns for protection. Yet the likelihood of personal disaster from possession of guns far exceeds the likelihood of protection. Guns increase the probability of homicide among family members and friends.

"And far more homeowners and family members are killed in gun accidents than by burglars and robbers."

Lunde concludes it might be impossible to "disarm" the millions of Americans who own guns. There are at least 50 million guns in the hands of civilians, and estimates run as high as 200 million.

But instead of licensing laws which seem to be favored in many states, Lunde supports restrictions on the manufacture and importing of both handguns and ammunition.

Lunde's book advances these conclusions among others:

1. Murder rates vary geographically. You are most likely to die young if you live in the South, where 13 out of every 100,000 persons are murdered each year. New Englanders have the best odds. In that part of the country only four out of every 100,000 persons die violently each year. Forty-four percent of all recent murders occurred in Southern states, 22 percent in North Central states, 19 percent in Northeastern states, and 15 percent in Western states.

2. Murder rates climb as population density increases. If you live in a large city, your chances of being murdered are twice those for a rural or suburban resident.

3. Men used to dominate the murder statistics, but women are changing this pattern. In 1950, less than 20 percent of all murderers were women. Now, that figure has inched up to about 25 percent.

4. Murder statistics also vary according to the color of a person's skin. Blacks are a more likely target. Black men are 10 times more vulnerable than white males, and black females five times more in danger than white women. And the races keep murder mostly segregated. In more than nine out of 10 homicides, killer and victim are of the same race. In a few instances where racial lines are crossed, it's more often whites murdering blacks than the reverse.

5. Alcohol and murder are closely linked. In the majority of homicides, the person who kills has been drinking beforehand. Most of the murderers are not alcoholics, however.

6. There's no significant correlation, either positive or negative, between the threat of the death penalty and the homicide rate in the United States.

Lunde emphasizes he does not blame the murder rate on dissatisfaction alone.

"Even changes in child-rearing practices have contributed to the holocaust," he writes. "Permissive parents are less likely to insist that children develop and use internal constraints.

"Organized religion, an institution that taught self-restraint and accountability, reaches fewer and fewer young people.

"Corruption in government makes it easier for people to blame external forces for hard times. Many have forgotten and some never realized that 'there is no free lunch.'

"If we continue to demand as rights what actually are privileges, we will continue to kill each other in frustration."

STANFORD –

Stanford's Lane Medical Library is suffering from an epidemic of damage to its scientific and medical journals, according to Peter Stangl, director of the library.

There has been a rash of page tearing and cutting of noncirculating material. An electronic device installed at the library entrance last year significantly reduced the losses of whole volumes. But mutilation of books has been increasing.

The costs of replacing the journals and repairing the ones damaged are "truly staggering," says Stangl.

Damage and loss of books is also a major problem at the main library and branches on campus.

According to Gloria Stockton, chief of circulation at the main library, "it's pretty bad. We've had a high number of cases of mutilation, particularly in scientific area journals." She reports that whole chapters have been ripped out of some books and journals, one of the hardest types of damage to replace.

One of the largest problems at Lane has been the purposeful tearing or cutting of articles from journals in the "green area" of the library, a noncirculating collection of journals published within the last 10 years.

Stangl is anxious to inform library users not only what expense the "ripping off" causes, but also what alternatives there are to damaging volumes.

He points out that if the volume searched for is not in the "green area," it can be checked out. If it is in the "green area," then there is a good chance that another copy is in the second-copy collection, and can be checked out.

If there isn't a second copy, there are four coin-operated machines where a copy of the article can be made.

The extensive second-copy collection is located on the main floor of the library, towards the back. The library receives these copies as gifts. They are not bound and may be checked out.

The copy machines, which cost a nickel a page, are located on the lower floor of the library. In addition, an operator-attended machine is available from 8 a.m. to 4:30 p.m. daily for larger copy needs.

When a journal is damaged by pages being pulled out, the library must go to great lengths to replace it, sometimes having to request it through interlibrary loan if it is no longer in print.

A single article torn from a bound journal can cost $25 or more to replace. Rebinding is more expensive than binding it originally. In addition, the volume is out of circulation for a length of time.

"Journals are not cheap," says Stangl. "We pay for close to 2,000 subscriptions a year, at an average cost of more than $40 each. We spend about $100,000 a year in journal subscriptions."

The problem of missing material is both costly and disruptive. "The library functions as a working resource," says Stangl, "not for replacing a user's personal collection. Restricting material to use in the library makes it available for many users."

The problem, he says, is that most people want the same few books. And it happens that the most heavily used texts and journals are the ones most likely to disappear or be destroyed, hurting the most people.

STANFORD--A reception honoring Dr. and Mrs. Alvin J. Cox, Jr. was held Friday (June 27) at the Stanford Faculty Club.

The reception, attended by more than 200 faculty and former dermatology residents, featured the presentation of an oil portrait of Dr. Cox painted by San Francisco artist George Sheppard.

The portrait was commissioned by members of the dermatology faculty and former students of Dr. Cox. It will be hung along with the portraits of other noted Stanford medical school professors in the Medical Center.

Dr. Cox came to Stanford as a freshman in 1923 and has been associated continuously with Stanford for 52 years. He has been a faculty member for 42 years and has served as chairman of the Department of Pathology for 23 years.

In 1964 he joined the Dermatology Department to develop a dermatopathology laboratory and to do research in skin biology. He is a professor of pathology emeritus in the Department of Dermatology, and he is still actively engaged in research and teaching at Stanford.

Dr. Eugene M. Farber, chairman of the Department of Dermatology, said Dr. Cox trained several generations of pathologists and has been a "meticulous, painstaking and extraordinary teacher."

Dr. Cox and two colleagues in the early forties discovered a chemical carcinogen, 2-acetamino fluorene, but it was not until 1966 that his work received worldwide attention," Farber said. "This was at a time cancer researchers began to study environmental hazards and they referred back to the pioneering effort of Dr. Cox."

In 1973 Dr. Cox was elected president of the American Society of Dermatopathologists.

Among guests who attended the reception were Dr. and Mrs. Loren "Yank" Chandler of Palo Alto. Dr. Chandler, professor of surgery emeritus, was dean of the Medical School for 20 years when it was located in San Francisco; San Francisco artist George Sheppard, and Dr. Clayton Rich, vice-president for medical affairs and dean of the Stanford medical school.

The program also featured a song recital by Lorene Adams of Atherton, soprano and soloist with the San Francisco Symphony. She was accompanied on the piano by her husband, Dr. Robert M. Adams, a clinical assistant professor of dermatology at Stanford.

STANFORD--New hope for successful treatment of general virus infections in humans was revealed Friday (August 29) at Stanford University during an international symposium for antiviral agents.

Leading infectious disease researchers reported that in early trials with patients, two substances for the first time seem capable of altering active virus infections. They emphasized, however, that the results are still preliminary and that more comprehensive studies are needed to determine the value of these therapies for widespread use.

Vaccines have been developed to prevent various virus infections. However, few agents are available to effectively control ongoing infections the way antibiotics can fight bacterial infections. Two substances have shown promise in recent years.

They are a protein called interferon, which is produced by the body's defense system to help fight disease, and a drug known as adenine arabinoside (ara-A) which can be manufactured synthetically.

Dr. Thomas Merigan, Jr., head of infectious diseases at Stanford School of Medicine, reported that in preliminary observations interferon seemed to modify the severity of certain virus diseases in cancer patients. Viral infections are usually self-limiting in healthy humans, but they can be life-threatening in cancer patients whose body resistance is low.

In another study, ara-A promoted the healing of shingles in cancer patients, according to Dr. Richard Whitley of the University of Alabama. Shingles, caused by the herpes zoster virus, is a painful condition in which skin blisters erupt along the course of a nerve.

Cancer patients at Stanford, Children's Hospital at Stanford, the University of California, Davis and St. Jude Children's Hospital in Tennessee were studied by Merigan and his colleagues Drs. Kenneth Rand, Paul Abdallah, George Jordan, Sandor Feldman and Richard Fried. Their work was supported by the National Institute of Allergy and Infectious Diseases (NIAID), of the National Institutes of Health.

In one group of 17 leukemia patients with chicken pox, those who were administered interferon had fewer complications due to spread to other organs than those given a placebo.

Another group of 55 patients with cancer of the lymphatic system had shingles. Organ complications from the virus were five times more frequent in patients who did not receive interferon than in those who did. Interferon patients also seemed to have less severe pain from nerve involvement.

Interferon is produced naturally by the immune system to limit the spread of virus infections and can be obtained from human white blood cells. It is also thought to be helpful in reducing the severity of the common cold and other upper respiratory tract infections caused by viruses.

-more-

However, studies have been limited because the protein is difficult to prepare in quantity in cultured cells. Merigan is confident that with improved production and purification techniques, adequate supplies of interferon will be available for further testing

The ara-A study, which involved 87 cancer patients at 10 different hospitals, marks the first collaborative effort to assess the effectiveness of the drug in treating systemic viral diseases. Whitley and Drs. Charles Alford, Jr., of Alabama, and George Galasso of the NIAID, are the coordinators of this study.

The patients were divided into two random groups: 47 were administered ara-A for five days followed by a placebo; the other 40 were treated with the opposite regime. Patients who received the drug the first five days of infection seemed to heal faster. The most favorable responses were in patients under 38 years old who had infections for less than six days, and in those who had lymphomas.

Ara-A acts at the cellular level by inhibiting viral replication, Whitley said. Additional studies are needed to verify these encouraging early results and to determine the long-term effects of ara-A, he added.

The drug, produced by Parke-Davis Laboratories, is available for a large-scale testing program under the auspices of the NIAID that involves 21 institutions throughout the country.

It has also been found useful as a topical application for treating eye infections caused by herpes simplex virus, according to two studies reported at the symposium yesterday.

Dr Deborah Pavan-Langston of the Massachusetts Eye and Ear Infirmary reported the results of a five-year study of ara-A on 315 patients with inflammed corneas from the herpes simplex virus. The drug, applied locally, proved "to be an effective nontoxic antiviral and an excellent alternative to IDU," (iododeoxyuradine) the drug more conventionally used, but which often causes complications, she said.

In another study at Moorfields Eye Hospital in London, England, corneal ulcers from herpes simplex which had failed to heal with IDU healed well after application of ara-A in 48 patients, Dr. Barrie Jones told the symposium.

Some 300 physicians and researchers have been attending the symposium on antiviral substances with clinical potential at Stanford this week. It is sponsored by the NIAID and Stanford University School of Medicine.

STANFORD--Physicians attending a symposium on antiviral agents at Stanford were cautioned Thursday (August 28) against the use of a popular treatment for herpes simplex, a virus which causes blisters around the mouth (cold sores) and genital area.

A recent study showed that neutral red dye and light, a therapy widely used by dermatologists against herpes simplex infections, is no more effective than a placebo, it was reported.

One of the investigators, Dr. Martin Myers of the University of Iowa, recommended that routine use of neutral red and similar dyes be discontinued until their efficacy and safety can be proved.

The combination of neutral red dye and light for herpes simplex has been used increasingly in the past couple of years after it was demonstrated to be effective in test tube studies. In tissue culture, neutral red, a photoactive dye, sensitizes the herpes simplex virus so that it does not reproduce on exposure to light.

For treatment, lesions around the mouth or genital area are painted with neutral red and then exposed to light. The procedure, thought to be safe, became controversial recently when researchers suggested there might be unknown long-term hazards, including the possibility of cancer, from its use. Nothing definite, however, has been shown.

Because of the controversy, Myers and his colleagues--Drs. Michael Oxman, Joan Clark and Kenneth Arndt, all of Harvard Medical School--undertook a comprehensive controlled study in Boston of neutral red therapy.

Ninety-six patients with a total of 170 episodes of recurrent herpes simplex infections were treated. Lesions were painted with either neutral red or a placebo dye and then exposed to light.

Neutral red "had no significant effect on the rate of resolution of herpetic lesions or on the incidence of subsequent recurrences," according to the investigators.

"The blisters eventually disappear and neutral red therapy does not make them heal any faster," Myers noted. "Nor does it seem to prevent recurrence."

Since the study failed to demonstrate any advantage of neutral red treatment and there are still unresolved questions about potentially harmful effects, Myers and his colleagues suggest that it no longer be used routinely.

STANFORD--"Effective treatment of even some of the many viral infections would change the course of medical care as did the advent of (antibiotics) in the 1930's and 40's," a leading health administrator told an international gathering of infectious disease research experts Tuesday (August 26) at Stanford University.

Dr. Dorland Davis, retiring director of the National Institute of Allergy and Infectious Diseases (NIAID) of the National Institutes of Health addressed the opening of a symposium on antivirals with clinical potential.

Although there are vaccines to prevent various virus infections, few agents have proved successful in treating infections once they occur. However, studies over the last few years provide new promise that certain substances may help control active viral infections in humans.

The impact of virus diseases on the health of the nation is substantial, Davis said, and he called on participants to continue the search for effective ways to combat these diseases. He pointed out that influenza and other respiratory conditions, including the common cold, account for one third of the visits to private physicians each year in this country.

The symposium is sponsored by the NIAID and Stanford University in conjunction with 22 drug companies. Dr. Thomas Merigan, Jr., professor of medicine and head of the division of infectious diseases at the School of Medicine is chairman.

The results of studies with interferon--a natural body protein, and adenine arabinoside--a synthetic drug, in treating virus diseases will be reported at the meeting. Additional topics presented include evaluation of other therpies for respiratory viral problems, herpes and other specific virus infections as well as the development of animal model systems for further investigations.

Some 300 representatives from 19 countries including the USSR are participating in the four-day symposium, which is being held at Bishop Auditorium on the Stanford campus.

The conference is dedicated to Dr. Dorland Davis who was instrumental in establishing a comprehensive federal program to support research on antiviral substances during his tenure as NIAID director for the past 11 years.

STANFORD--A fund has been established at Stanford University School of Medicine in memory of Dr. Judith Graham Pool to support students and physicians studying in the hematology field.

Dr. Pool, 56, professor of medicine at Stanford and an internationally recognized hemophilia researcher, died July 13 after an extended illness. She had been a member of the Stanford medical faculty since 1957.

The fund, which will be comprised of private contributions, is being administered by Dr. Stanley L. Schrier, professor of medicine and head of the Division of Hematology at Stanford. He is being assisted by Dr. Daniel Federman, professor of medicine and executive chairman of the Department of Medicine, and Dr. Clayton Rich, dean of the school of medicine and vice president for medical affairs.

Undergraduate students, medical students, housestaff physicians and fellows, and gifted high school students will be eligible for training under the Pool Fund. Research and seminars will also be supported by it.

Dr. Pool is credited with developing a simple method for extracting from normal blood the protein (called Factor VIII) needed by hemophiliac patients.

Availability of the missing clotting factor enables hemophiliac patients to treat themselves at home with injections, reducing both the length of hospitalization and treatment costs.

She had recently been investigating another concentrate which may offer hope to a small percentage of hemophilia patients who develop complications from the standard Factor VIII treatments.

Dr. Pool earned her bachelor's degree in 1939 and her Ph.D. in physiology in 1946, both from the University of Chicago. She later taught at Hobart College in Geneva, N.Y. prior to joining Stanford.

STANFORD--Malpractice insurance rates for Stanford University Hospital and Clinics will increase by nearly $1 million yearly on November 1, bringing the Hospital's rate to approximately $2.4 million.

Stanford Hospital is one of many members of the California Hospital Association insurance group which received the news last week.

Although the impact of the increase will be felt in higher daily room rates, not all patients will bear the full burden. Currently, there are limits on the amount that hospitals can be reimbursed for care of Medicare and Medi-Cal patients.

James Stanford, Medical Center Director of Finance, admits that "This represents a major increase in costs to patients," but he also notes that it comes when costs are already high, "and there is tremendous pressure from state and federal governments to keep costs down."

The new insurance rate is the second this year. In January there was a 100 percent increase over the 1974 rate.

But the future may hold even worse news. According to James Stanford there is no guarantee that the rate won't go up again before the end of the year, since the bills are sent monthly. "My best guess is that it will be even worse in the near future," he says.

The new increase applies to all member hospitals of the CHA insurance group. But because the rates are based on the number of beds, outpatient visits, staff, and surgeries, the dollar amount is even greater for Stanford than for other hospitals.

The CHA insurance program, with member hospitals throughout the state, is administered by Walker & Company of Los Angeles, insurance brokers. Coverage includes Hospital and Clinic staff and the Medical School faculty.

STANFORD--Fifteen physicians on the Stanford University Hospital clinical staff have been denied court injunctions which would have allowed them to practice at the Hospital without malpractice insurance.

The court also denied a request that it prohibit the insurance carriers from canceling the hospital's malpractice insurance if uninsured doctors use the facilities.

Both decisions were made by Judge John M. Brenner in Santa Clara County Superior Court in Palo Alto on Friday, September 26.

The doctors' suit was a result of dramatic increases in malpractice insurance costs. Last April insurance carriers notified hospitals throughout the state that they must require doctors using the hospital facilities to have individual policies.

Stanford Hospital is one of many members of the California Hospital Association insurance group, with coverage for all Hospital and Clinic staff and Medical School fulltime faculty, but not covering community physicians who use the Hospital.

In his decision, Brenner noted that the requirement that these doctors carry such insurance would be an extremely heavy burden to some, but the insurance companies have said they will cancel the hospital's insurance if physicians practice without coverage.

Brenner said that if the 15 uninsured doctors used the hospital, the hospital would then lose its liability insurance, and would "thereby be placed in a position where it could not safely continue its normal operations."

Brenner said the court could not tell the insurance carrier not to cancel the hospital's insurance. "It seems to this court, and the court holds, that a doctor does not have the right to put a hospital in the position of having to pay the full cost of joint doctor-hospital negligence .... It is reasonable for the hospital to require that doctors who want to use the hospital facilities must be financially able to meet their share of any such potential joint liability."

STANFORD –

Dr. Daniel D. Federman, professor and chairman of the Department of Medicine at Stanford University School of Medicine, has been named the Arthur L. Bloomfield Professor of Medicine.

The appointment, effective immediately, was announced Wednesday, Sept. 11, by Dr. Clayton Rich, vice-president for medical affairs and dean of the Medical School.

Federman, 47, succeeds Dr. David A. Rytand, who held the endowed chair from 1958 until he became Bloomfield Professor emeritus Sept. 1 this year.

A nationally-known expert in clinical endocrinology, Federman came to Stanford as head of the medicine department in 1973. He was previously associate professor of medicine and associate dean of continuing education at Harvard Medical School.

Federman is widely recognized for his outstanding contributions to teaching and his cogent approach to improved medical education. His teaching was honored twice by Stanford students: with the Henry J. Kaiser award for excellence in teaching in 1974 and with the Arthur L. Bloomfield Award in recognition of excellence in clinical teaching in 1975. He has also been similarly honored by Harvard medical students.

One of the challenges facing medical educators today, Federman said when he accepted executive responsibility for the School's largest department, is to prepare students for the new demands being placed on physicians.

In the past two years he said in a recent interview, "The Stanford medicine department has concentrated on meeting the changing trends in clinical medicine, such as the increased interest in primary care, without threatening its subspecialty strength and without compromising its scientific standards."

His research interests have been mainly concerned with hormonal and genetic influences on human sexual development. One of his major scientific contributions has been studies of abnormal gonadal physiology seen in clinical conditions. His textbook, *Abnormal Sexual Development: A Genetic and Endocrine Approach to Differential Diagnosis,* published in 1967, has been widely acclaimed.

With colleagues at Harvard, he defined a new hereditary disorder of connective tissue characterized by dwarfism, joint stiffness, and eye defects. He was also among the first to describe translocation of a portion of the human Y chromosome.

Born in New York, Federman is an alumnus of Harvard, receiving his A.B. in 1949 and his M.D. in 1953. He took an internship and residency in medicine at the Massachusetts General Hospital.

After completing additional training at the National Institute of Arthritis and Metabolic Diseases in Bethesda, Maryland, and at the University College Hospital Medical School in London, he returned to Harvard.

In addition to his faculty responsibilities at Harvard, he was assistant chief of medical services and chairman of the committee on teaching and education at the Massachusetts General Hospital.

The Bloomfield Professorship was established in 1954 in honor of Dr. Arthur L. Bloomfield who retired as head of the medicine department that year after 26 years on the Stanford medical faculty. Bloomfield died in 1964.

STANFORD--Tobacco smoking is a "unique and hazardous form of indoor air pollution" that is likely to worsen breathing problems in non-smokers, according to a Stanford medical professor.

Furthermore, according to Dr. William J. Sayer, clinical assistant professor of medicine at Stanford Medical School, smoking in a poorly ventilated room or car causes carbon monoxide levels "well within the range known to cause impairment of visual acuity" and balance.

He added that such levels "could be lethal for the bystander who suffers from arteriosclerotic heart disease."

Also writing in the Western Journal of Medicine, Sayer said other non-smokers susceptible to tobacco smoke are those with bronchitis, asthma, allergies and other respiratory diseases.

Sayer noted that carbon monoxide in the air near a smoker can be increased from an atmosphere value of one to three parts per million to "transient peaks" exceeding 90 parts per million. At the same time, nitrogen dioxide, an acutely irritating gas, "exists in cigarette smoke in amounts 160 times greater than levels considered safe for extended exposure," he said.

"It is no cause for wonder," he added, "that the Surgeon General of the United States has declared a Bill of Rights for the non-smoker."

STANFORD--Dr. David A. Hamburg, Reed-Hodgson professor of human biology and professor of psychiatry at Stanford University School of Medicine has been appointed president of the Institute of Medicine.

The appointment was announced Friday, Oct. 31, by Dr. Philip Handler, president of the National Academy of Sciences in Washington, D.C.

Hamburg will be the Institute's third president, succeeding Dr. Donald S. Fredrickson, who left the office last July to become director of the National Institutes of Health.

The Institute of Medicine is composed of distinguished biomedical scientists, health professionals, and persons who have made contributions to public health. Its work is concerned with analysis of public policy problems in the health field. Hamburg became a member of the Institute of Medicine in its first election in 1971.

Hamburg will be taking leave of absence from Stanford at the end of the present academic year to take up his new position.

He came to Stanford in 1961 as professor and chairman of what is now the Department of Psychiatry and Behavioral Sciences.

For 11 years he directed the department's development into a nationally recognized center of research on psychiatric problems.

Hamburg stepped down from the chairmanship in 1972 to devote his efforts to the development of new programs including the Stanford Laboratory of Stress and Conflict, the undergraduate Human Biology Program, and the Program on Science, Technology and Society at the nearby Center for Advanced Study in the Behavioral Sciences.

His research contributions have centered on behavior under stress, especially hormonal responses and ways of coping with difficult situations. He was one of the first in psychiatry to call attention to the scientific value of studies on monkeys and apes.

In this context, he established the Stanford Outdoor Primate Facility, and a program of research and education on chimpanzees and baboons in East Africa.

His wife, Dr. Beatrix Hamburg, is an associate professor of psychiatry and behavioral sciences at Stanford. She has done pioneering work on problems of early adolescence and will be enlarging the scope of this work in a new position at the National Institute of Mental Health.

STANFORD--A Stanford physician says that over-the-counter drugs should be better labeled, including information about such commonly consumed ingredients as caffeine and aspirin.

"Packaging and advertising of non-prescription medicines are woefully lacking in pertinent facts," said Dr. William H. Forrest, Jr., associate professor of anesthesia.

He spoke today (Oct. 29) before the monopoly subcommittee of the Senate Small Business Committee in Washington, D.C.

Forrest called for more complete labeling that would enable users to directly associate the brand name with its contents and their effects.

Labels, he said, should include a listing of every active ingredient, giving the amount of each dose in milligrams. They should also give a brief common definition of why an ingredient is in the product, and list conditions which might alter the main effect of the medicine.

He called for providing this information in type much larger than that now used to list ingredients, and placing all information on the outside of the package, as well as in every advertisement.

He also recommended that supervision of such advertising be given to the Food and Drug Administration, instead of the Federal Trade Commission.

As an example, Forrest pointed out that caffeine, like all drugs that are affected by the user's mood at the time, cannot be guaranteed to produce the same effect in every person, or in the same person every time.

Almost a third of current over-the-counter pain compounds contain some caffeine.

Forrest pointed out that the stimulant effect of caffeine-containing medicine is influenced by how much coffee the individual drinks.

-more-

"One might expect medication containing caffeine to have less of a stimulant effect on a heavy coffee drinker than on a light coffee drinker or some one who used no coffee at all," he said. Medication containing caffeine should carry a warning that it might, under certain circumstances, have no effect or even the opposite effect on coffee drinkers, he said.

"In other words," said Forrest, "if you took one of these preparations at bedtime for a headache, you could conceivably find your headache gone after a while, but you might be lying in bed wide awake because of the caffeine."

Using another example, he said, "It is clear that certain individuals should not take aspirin because it irritates their stomachs and may even cause ulceration and bleeding. And yet you seldom see warnings about these hazards on any aspirin bottle or in any advertisement for medicine containing aspirin."

In addition, Forrest recommends that labels provide some description of the effect of active ingredients, such as "an antihistamine," "a sedative," or "analgesic" after the technical name.

Forrest believes that "most over-the-counter products are not problems in respect to safety." The Food and Drug Administration, he says, "already has good machinery for judging efficacy and safety.

"The real problem is that the public needs better information in advertising and at the potential point of sale. It needs facts presented in clear, non-technical language, with the full story told each time the drug is promoted."

FOR IMMEDIATE RELEASE

STANFORD –

"I favor the education of women, believe in co-education and, in fact, believe fully in the right of women to have the franchise. . . . A woman can be educated and even vote, if you please, and still be a womanly woman."

With these words, Jane Stanford, cofounder of Stanford University, expressed her views of women's rights during the National Woman Suffrage Association meeting in San Francisco in 1901.

Her legacy in the cause of women's rights and education is now detailed in a new book, *Jane Stanford: Her Life and Letters* (179 pp., Stanford Alumni Association, $8.95, cloth, $6.95, paper) by Gunther W. Nagel.

The book is also a "first"—the first publication of Mrs. Stanford's letters in which she herself is allowed to tell her story.

Nagel, an emeritus Stanford clinical professor of surgery and San Francisco author, spent more more than two years in the University archives studying Jane Stanford's letters.

He has connected them with explanatory bridges and footnotes, depicting Jane Stanford's role not only in keeping the fledgling institution going in those early days but also in shaping its future.

"Her letters," Nagel states, "reveal a portrait of a remarkable woman. They have an impact and reality no historian can match."

Jane Stanford was born Jane Eliza Lathrop in Albany, New York, in 1828. One of six children of a successful merchant, she started schooling at the time the first stirrings of the women's movement began in America.

One of the movement's original goals was an education for women commensurate with that of men. By the time Senator and Mrs. Leland Stanford had founded Stanford University she wrote:

"Nobody appreciates more than I do the advantages of an education to those of my sex. Nor does anybody realize more than I do the effect on society of an educated and enlightened womanhood."

A sincere religious feeling and belief in old-fashioned virtues came naturally with Mrs. Stanford's upbringing. "I hope to see departments of philosophy and ethics established," she wrote in 1905. "Science must not overbalance the humanities as at present."

Jane Stanford from the start envisioned a university being in the forefront of changes taking place in higher education. There was to be a departure from the rigid course of study of the classical period, with its class distinctions, toward more practical courses and the ideas of freedom of choice.

Stanford University, writes Nagel, helped lead the way by setting up new guideposts with new conventions and customs in an environment far removed from the trappings of tradition.

Mrs. Stanford expressed her feelings on this subject in a letter to Stanford's first president, David Starr Jordan:

(more)

"I was quite surprised to find that any ceremony was expected in laying the cornerstone of the new library. . . . I prefer to do what is to be done in a quiet, unpretentious, unsensational manner. . . . One of the pleasures of adding to and beautifying the buildings is to do it without the blowing of trumpets. . . ."

In another letter she wrote: "There is one thing that troubles me very much, this constant comparison of our University with Berkeley, Harvard, Yale, Cornell, etc. Always remember we are simply a unique institution of our own; not trying to compete with any other in the world. . . ."

Jane Stanford respected President Jordan's wishes, but she was not sure about the faculty. "The professors as a rule (but there are exceptions and golden exceptions) think they want many things they can do without. It is so easy to spend money, but, oh, how hard it is to get it you and I know."

Mrs. Stanford's severest test of will came after Senator Stanford's death, when the country was in a financial panic, and the government initiated a suit attempting to establish the estate's liability for more than $15 million in Central Pacific Railroad construction loans.

When a group of bankers and lawyers told her point-blank, "The University must be closed!" she refused to be intimidated. "Do you think I believe that my husband's carefully laid plans can wholly miscarry?" she replied. They would learn eventually what a determined woman could do.

Stanford's doors were never closed, writes Nagel. "The University which Senator and Mrs. Stanford dedicated with high hopes became one of the important centers of learning in the world."

Below are excerpts of Mrs. Stanford's views:

On equality: "It shall be the duty of the University authorities to prohibit excessive expenditures and other excesses on the part of students, and the formation or growth of any organization, custom, or social function that tends to the development of exclusive or undemocratic castes."

On freedom of speech: "I feel that all American citizens are entitled to their own opinions and to express them if they feel inclined to do so. That is the blessed liberty that American freedom gives to us all.

"One of the most beautiful features of the gift of my husband is his insertion among its laws that the purposes of the University are 'to promote the public welfare by exercising an influence in behalf of humanity and civilization, teaching the blessings of liberty regulated by law, and inculcating love and reverence for the great principles of government as derived from the inalienable rights of man. . . .' "

On development of character: "Always be gentle in manner, resolute in purpose, and you will develop characters on which others can depend; and you can safely dispense with the more brilliant qualities if you can be depended upon for truthfulness, honesty of purpose; and each example of a good student will reach out and have an undying influence."

On the dangers of the politicization of the University: "As you know, my husband was an ardent Republican. He never flaunted the vices or the mistakes of his party leaders before the public. He praised their virtues and deplored in secret their vices, but he never would have used the president of a great University which he founded to further his political views or his enmities or his prejudices."

On professors: "I consider the lectures and opinions of a professor secondary to those of a president of a university."

STANFORD –

A new department of neurobiology which will concentrate on the brain and nervous system has been established at Stanford University School of Medicine.

Formation of the department was announced Wednesday, Oct. 22, by Dr. Clayton Rich, vice-president for medical affairs and dean of the medical school.

Dr. Eric Shooter, professor of genetics and biochemistry and a noted molecular neurobiologist, has been appointed professor of neurobiology and chairman of the department, effective immediately. Other faculty members are Drs. Denis Baylor and John Nicholls.

The department will be located in the Sherman Fairchild Center which is scheduled for completion in September 1976.

According to Shooter, the department will act as a focal point for teaching and research activities in the basic neurosciences at the medical school. It will include aspects of anatomy, physiology and biochemistry relating to the nervous system and will also coordinate the interdepartmental Ph.D. program in neuro- and biobehavioral sciences organized by the medical school and university in 1963.

Shooter noted that the field of neurobiology promises major advances in the coming decades. "Neurobiology today is at the forefront of the life sciences. Technological advances in areas such as molecular biology, electron microscopy and computer science make it possible to study how the nervous system functions not only at the cellular and molecular level, but also at higher levels as in perception and movement control," he said.

Research in the new department will include studies of nerve impulse transmission, of nerve connections and pathways in the visual system, and of nerve cell development.

Shooter is recognized for his work on nerve growth factor, a protein that affects the development, differentiation and maintenance of nerve cells. He and his colleagues have isolated and recently crystallized the protein and are studying its three dimensional structure in an effort to better understand its role in nerve development.

A member of the Stanford faculty since 1963, Shooter received his Ph.D. in 1950 from Cambridge University in England. In 1964 he was awarded a doctor of science degree from the University of London for distinguished work in biochemistry.

Shooter is an editor of *Neurobiology*, and *Journal of Biological Chemistry*, and a member of several professional committees and societies. He is also chairman of the Committee on the Teaching and Research Manpower Needs in Basic and Communicative Sciences of the National Research Council's Assembly of Life Sciences.

STANFORD--Stanford scientists are working on a new imaging system that may provide doctors with a chest x-ray with the bone structure eliminated, making cancers or lung tumors clearly visible.

When developed, the new x-ray system could provide isolated images of specific materials, such as bone, soft tissues, or the circulation system, on conventional x-ray film and without any more risk to the patient then standard x-rays.

Dr. Albert Macovski, adjunct professor of electrical engineering and radiology at Stanford, reported the progress in this work at the annual meeting of the Optical Society of America today (Oct. 22) in Boston.

According to Macovski, x-rays utilize a spectrum of energy ranges. Certain energy levels act specific ways on different materials. For example, the absorption region for contrast material, like iodine and barium, occurs in specific regions of the energy spectrum. Lower energy levels, which are more responsive to bones and calcifications, could be delineated from higher energy regions.

With the new x-ray system being studied, information gained at certain energy levels can be encoded on a standard radiology film, then this information can be decoded to provide isolated images of specific body materials.

Says Macovski, "Grating structures, containing alternate stripes of different materials, are placed in the path of the x-ray beam. These allow the encoding of a wide variety of energy spectrum information

"This information, when decoded and processed allows the radiologist to delineate various body structures and administered contrast material (like iodine or barium) in a manner that was not possible before

"The ability to delineate these structures should significantly improve the diagnosis," he says.

He cites the advantage to the radiologist who could look through the bony pattern of a chest x-ray and see soft tissue, lesions, and airways which underlie the bone, or for example, lung tumors under the ribs.

Radiation exposure for the patient would be no higher than in standard radiography. A single exposure made through the grating would separate the various components of the "picture."

An important application being investigated is the system's ability to see iodine contrast material used to study the cardiovascular system. Catheterization could be replaced by a simple intravenous injection of iodine, because of the sensitivity of the system in isolating images of this material.

Dr. Macovski and his colleagues have simulated trials of the system, and hope to apply it in animal studies during the next few months. its use for patient diagnosis would come at a later time.

The investigation is being supported by a grant (GM 20984) from the National Institutes of Health.

FOR IMMEDIATE RELEASE
STANFORD –

Nobel Laureate Gerald M. Edelman of Rockefeller University, New York, will deliver the third annual Linus Pauling Lecture at 4 p.m. Thursday, Oct. 23, in Room 420-040 of the Jordan Psychology Building on the Stanford University campus.

Dr. Edelman will discuss "Surface Modulation and the Control of Cell Function." The lecture is sponsored by the Departments of Biochemistry, Biology, Chemistry, and Pharmacology, and the Stanford Magnetic Resonance Laboratory. It is open to the public.

Dr. Edelman, 1972 Nobel winner, is engaged in the study of the structure of immunoglobulins and the genetics of the immune response, and the study of cell surface receptors and the control of cell division.

He holds the M.D. from the University of Pennsylvania School of Medicine, and the Ph.D. from the Rockefeller Institute. Since 1964 he has been Vincent Astor Distinguished Professor at Rockefeller University. Dr. Edelman is a member of numerous scientific societies, and holds several honorary degrees.

The Linus Pauling Lecture was established in 1973 in Dr. Pauling's honor by his friends and colleagues. Dr. Pauling delivered the first lecture, and Dr. Arthur Kornberg, holder of the endowed Emma Pfeiffer Merner professorship of biochemistry, and 1959 Nobel Prize winner, delivered the 1974 address. The topics are chosen in areas of molecular biology related to Pauling's work.

Dr. Pauling, Stanford professor of chemistry, won the Nobel Peace Prize in 1962, and the Nobel Prize in Chemistry in 1954.

STANFORD--Stanford University has announced plans for seeking construction of a new, approximately 48,465 square foot, cancer research building to be located on Governor's Lane near the Medical Center.

Total cost is estimated at $11.1 million. Support is sought from the National Cancer Institute (NCI) and through private gifts.

The new building would be the second increment in the development of the Governor's Lane complex, compatible with the long-range plan for that site. It would be located adjacent to the Louis B. Mayer Cancer Biology Research Laboratory, which houses a new program in cancer research under the direction of Dr. Henry S. Kaplan, Stanford professor of radiology.

The new facility will house investigators in medical oncology, radiobiology and tumor immunology and virology, now located in the main medical center building. A portion of the grant requested from NCI would allow renovation of the vacated facilities for other cancer-related programs in basic immunology and virology.

The new construction is expected to remedy the severely limited and fragmented space for the ongoing cancer research in the main medical center building, as well as strengthen and expand research, clinical investigative and educational programs in cancer.

Communications with appropriate agencies are underway, and Stanford has prepared an environmental assessment statement.

STANFORD--Stanford University Hospital daily room rates will increase two percent beginning November 1.

The increase, according to Paul Hofmann, director of the Hospital and Clinics, is for the purpose of covering an almost $1 million increase in the Hospital's annual malpractice insurance rate, which is effective on the same date. Malpractice insurance rate increases of 66 percent will be implemented for all hospitals participating in the California Hospital Association program. Hofmann emphasized that the room rate increase would have been substantially greater if Stanford did not require practicing physicians to have malpractice insurance.

Action was taken at this week's meeting of the Hospital's board of directors. The new rates add approximately $3 to the average daily room rate.

New daily medical-surgical rates will be $120 for ward, $130 for semi-private room, and $147 for a private room.

Daily rates for patients using services of the housestaff (interns and residents) are approximately $12.50 higher. The use of housestaff services is determined by the patient's attending physician.

New rates for the intensive care units will also increase two percent, to $398, and intermediate intensive care will rise to $289.50.

Last July the Hospital increased its room rates an average 10 percent to reflect raises in salaries of employees as well as the inflationary cost increases in food, medical supplies, and utilities. A major increase in malpractice insurance had not been expected at that time.

STANFORD--A new technique for monitoring heart function for the lifetime of the patient after open heart surgery has been developed by the Palo Alto Medical Research Foundation working in collaboration with researchers from the Stanford University School of Medicine.

The technique consists of implanting small metal coils at strategic points in the patient's heart muscle during the operation, then using them in conjunction with x-ray video disc pictures to monitor changes in the heart.

The system has been used for nearly 19 months at Stanford University Hospital, the researchers reported Monday (Oct. 13) at the meeting of the American College of Surgeons in San Francisco.

The researchers are Dr. Neil Ingels and George Daughters of the Palo Alto Medical Research Foundation, and Drs. Edward Stinson, Edwin Alderman, Lewis Wexler, Philip Oyer, Randall Griepp, Jack Copeland, and Norman Shumway of Stanford.

According to their report, markers have been placed in 23 heart transplant patients and in 20 patients who underwent coronary artery bypass graft and valve replacement surgery.

The tiny metal coils--about the diameter of a needle and about 1/16th of an inch long--can be inserted easily in the muscle fiber of the heart by the surgeon in a matter of minutes.

The coils are made of tantalum, an inert metal that creates no reaction within the body and can be left in place without complications for a lifetime.

Using a sequence of x-ray photos taken at any time after surgery, in conjunction with video monitors and a computer, the researchers can determine--within an hour of photo taking--how each segment of the heart is working, how much blood the heart contains, how much it is pumping, and the contraction time of the muscle.

-more-

222--Metal Coils

By comparing one set of photos with a later one, they can determine if the heart is getting larger or smaller, if rejection of the transplanted heart is taking place, and how fast heart deterioration or improvement is occuring.

The condition of the patient's heart can be checked at frequent intervals without any danger or discomfort to the patient merely by taking a three-second sequence of x-ray pictures.

The project has been funded by a grant to the Foundation from the National Heart and Lung Institute and by private funds. It is designed, according to the researchers, to further the study of the short-term recovery process after surgery, the effects of drugs and exercise in the hearts of patients, and the effects of the rejection process and anti-rejection drugs on the transplanted heart.

"The long-term course of cardiac function can be followed precisely and routinely over the patient's lifetime using this noninvasive technique," the report concluded.

STANFORD--Fifty community physicians, suspended last week for failure to meet Stanford University Hospital's malpractice insurance requirements, will have till October 30 to comply.

According to Dr. Clayton Rich, vice-president for medical affairs and dean of the School of Medicine, the effective date of suspension was changed at the request of several physicians.

"In addition," Dr. Rich said, "the hospital has now been informed that a failure on its part to enforce these requirements will not adversely affect the hospital's own insurance program until November 1.

"For these reasons the board of hospital directors, on the recommendation of the medical board, has approved such an extention to October 30."

Dr. Rich said he hoped that during the additional time physicians would reconsider the matter and obtain the insurance necessary to remain on the staff.

STANFORD--Treatment with high doses of radiation therapy are resulting in 62 percent of patients with nasopharynx cancer surviving at least five years, and 56 percent surviving at least 10 years, according to a Stanford Medical Center study.

The findings are based on 18 years experience with 82 patients treated by Stanford's medical linear accelerators. They reflect improvements in the survival rates from earlier studies that showed from 28 to 56 percent survival for five years.

Results of the study were presented today (October 9) at the annual meeting of the American Society of Therapeutic Radiologists in San Francisco. Authors of the report are Dr. Richard T. Hoppe, radiology fellow; Dr. Don R. Goffinet, assistant professor of radiology; and Dr. Malcolm A. Bagshaw, professor and chairman of the Department of Radiology at Stanford.

Cancer of the nasopharynx accounts for approximately 1.3 percent of all cancers.

The authors report that irradiation of adequate size to encompass all the disease as well as other areas of possible involvement with doses of 6500 to 7000 rads in six to seven weeks "can achieve cure in more than half of the patients with cancer of the nasopharynx."

According to Bagshaw, cancers of the nasopharynx are best treated with radiation therapy. This is because the location of the primary cancer and the high incidence of spread to other inaccessible sites make surgery almost impossible.

Fifty-seven men and 25 women, with a median age of 52 years, received high dose megavoltage irradiation on linear accelerators in the study.

Survival rates, says Bagshaw, depended on the initial extent of the disease. Five-year survival rates for first stage cancers were 76 percent; for second stage, 68 percent; and for third stage, 55 percen

Patients with uninvolved lymph nodes or only one nodal involvement did well (78 and 70 percent five-year survival), while patients with more nodal involvement did worse (39 to 42 percent five-year survival).

According to Bagshaw success has been particularly evident in first and second stage patients since 1967, when the use of larger radiation fields began. "The better results since then," he says, "are due to the larger volume radiation, allowing us to pick up microscopically involved areas."

The study was supported by grants from the National Cancer Institute and the National Institutes of Health.

STANFORD--A new laboratory, which will enable scientists to unlock the mysteries of tiny atoms that make up biological molecules, will be dedicated at Stanford University during a two-day conference Thursday through Friday (Oct. 9-10).

The international conference on molecular structural methods in biological research will begin at 9 a.m., Oct. 9, at Stanford Children's Hospital Auditorium. It is expected to attract more than 150 eminent chemical physicists, physical chemists, biochemists and biologists.

The Stanford Magnetic Resonance Laboratory, located in the Chemistry Building, will serve as a regional instrumentation center to aid scientists in their efforts to understand and conquer disease.

The facility, established with a joint award of $500,000 from the National Institutes of Health and the National Science Foundation, houses the first of the world's most powerful nuclear magnetic resonance spectrometers designed to the specifications of the Stanford group, according to Professor Oleg Jardetzky, director of the laboratory.

"So far," Dr. Jardetzky said, "46 scientists from the United States and abroad have used the facilities for exploratory experiments to evaluate the potential of high-frequency, high-resolution, nuclear magnetic resonance in the solution of chemical, biological, and medical problems."

A nuclear magnetic resonance spectrometer makes it possible for researchers to observe the magnetic properties of atoms in a molecule, and provide information which describes their spacial relationships and movements.

The technique allows scientists to "look" at structures many times smaller than can be seen with an electron microscope. In addition, it does not cause chemical alterations on the object being observed and can follow events in time and without interfering with the process.

-more-

For example, a scientist may label amino acids (the building blocks of proteins) with stable isotopes and can chart changes in protein structure which result from the effects of drugs or other chemical agents. The studies are important in understanding disease.

The facility, said Dr. Jardetzky, will be used to study the physical and chemical properties of certain important biological materials to increase understanding of the roles they play in life processes.

Specific projects include the study of mechanisms of genetic control, cell membranes, drugs and their effect on enzymes, and the geometry of protein molecules. Abnormally shaped proteins have been associated with hereditary diseases.

"The instrument will provide the only systematic approach by which scientists can get a better understanding of the basic mechanisms of certain diseases and to make drugs for their treatment," Dr. Jardetzky said.

Stanford's nuclear resonance spectrometer was built to operate at the highest frequencies that could be attained with available technology, he said. The instrument has a resolution of 360 MHz (Mega Herz) for hydrogen nuclei and 90 MHz for carbon-13. It was built for the new laboratory by Bruker Scientific, a company based in West Germany and Switzerland, and Oxford Instruments, Oxford, England. Since the Stanford installation a similarly powerful instrument was installed at Bell Laboratories, he said.

The discovery of nuclear magnetic resonance in 1945 was made almost simultaneously by Professor Felix Bloch at Stanford and Edward M. Purcell at Harvard. Professor Bloch, a Nobel Price winner, will speak at the meeting.

The laboratory operates under guidelines established by the Biotechnology Resources Branch of the NIH and an administrative committee. It is chaired by Dr. Jardetzky and includes Professors Robert L. Baldwin, and Harden M. McConnell of Stanford; Melvin P. Klein, University of California, Berkeley; and Manuel F. Morales, University of California Medical Center, San Francisco. Professor William F. Massy, Stanford vice-provost for research, serves as an ex-officio member.

STANFORD--A human cancer virus will be detected within the decade, a Stanford University scientist predicted Saturday (Oct. 4).

"This is my personal conviction," said Dr. Henry S. Kaplan, speaking at the dedication of the $1.2 million Louis B. Mayer Cancer Biology Building at Stanford.

Kaplan, Maureen Lyles D'Ambrogio Professor of Radiology, told 300 guests that research in the building will involve an intensive attack on the basic aspects of human lymphomas, with respect to their biologic nature, immunologic behavior, and the increasingly strong possibility they might be caused by viruses.

Basic to this work, he said, is the success he and his associates have had recently in growing in laboratory cultures the tumor cells from 15 different types of human malignant lymphomas.

He explained that the search for a cancer virus requires successful cultivation of cancer cells outside the body. Inside the body, many of these viruses induce antibody which binds to the virus and masks its detection.

"If we identify a virus in certain types of human cancer, such as the lymphomas, and grow the virus and purify it, the opportunity to do some practical things would become very real," he said.

"But we would have to prove beyond any reasonable doubt that the virus had something to do with the causation of the cancer from which it came," he added.

This would not be easy. Viruses are known to grow in cancers as "passengers." They like the environment of the cancer better than normal tissue.

"It would be important to prove first that any virus we may find is human, and not a contaminant," Kaplan said. "We have to show it isn't a passenger virus, and finally we have to find a causal relationship to the tumor."

-more-

All that would take a few years, he said. But if a human cancer virus were isolated, its components could be altered biochemically to function as a vaccine.

"If we reach that point, I think there is a good reason to believe cancer prevention might become possible on a mass scale," Kaplan said.

Isolating one human cancer virus will not eliminate all cancer, Kaplan cautioned. This is because each group of viruses produces only limited categories of cancers.

But the techniques developed from the original work could be used to isolate other viruses.

Dr. Frank J. Rauscher, Jr., director of the National Cancer Institute, said at the dedication that he had toured many facilities across the nation, but that he had "seen none better than this cancer research center."

Rauscher also called for an end to what he termed "halfway technology."

"We must do all we can for today's cancer patient and not worry only about tomorrow's patient, he said.

"We must also concentrate our efforts on the prevention of cancer by determining those who have high risk of cancer and have these people come in more often for a checkup."

University President Richard W. Lyman presented the building, and Robert Minge Brown, president of the Board of Trustees, made the acceptance speech. Melvyn, C. Ury, chairman of the Friends of Radiology Steering Committee, acknowledged the donors.

Faculty investigators who will work in the laboratory with Dr. Kaplan are Dr. Michael Feldman, visiting professor in cell biology, Weizmann Institute, Israel; and Drs. Zvi Y. Fuks, Marcia Bieber, Alain Decléve, Miriam Lieberman, and Peter Rosenthal.

The new laboratory was designed with special consideration for containment of biohazards. It was funded by the National Cancer Institute and gifts from the Louis B. Mayer Foundation, the San Francisco Foundation, and other private donors.

Transmitted by telephone Saturday (Oct. 4), 1975

STANFORD UNIVERSITY MEDICAL CENTER
News Bureau Stanford, California 94305

FOR INFORMATION CONTACT: Spyros Andreopoulos 415: 497-6911

STANFORD--Fifty community physicians on the staff of Stanford University Hospital have been suspended for failure to carry adequate malpractice insurance, officials said Thursday (Oct. 2).

Thirty of the suspended doctors are psychiatrists, five are general surgeons, and 15 are in other specialties. With few exceptions, most of them have only on occasion used Stanford, according to Dr. Robert H. Alway, medical director.

But more than 400 community physicians have now complied with the hospital bylaws requiring doctors to be insured in order to practice in the hospital, Dr. Alway said.

The new policy went into effect August 1. The hospital has been considering such a requirement in the interest of protecting its patients for some time, officials said. But their decision to impose it at this particular time was due in large part to insistence by the hospital's own insurance carrier.

According to the hospital, failure to comply would have resulted in cancellation of the Hospital's insurance or at the very least enormous increases in its premiums.

Officials also said that last spring, even before any insistence by their carriers, about 200 California hospitals had already required that their physicians be insured, and by now all California hospitals have such a requirement.

Stanford belongs to the California Hospital Association insurance group. The program is administered by Walker & Company of Los Angeles, insurance brokers.

The suspended physicians are reinstated as soon as they have adequate coverage, Dr. Alway said. The minimum individual coverage required is $1 million per malpractice case, and $1 million aggregate per year for all cases.

The major carrier for California hospitals has announced this week that institutions allowing uninsured doctors on their staffs would have to pay an additional premium because of the increased risk. The premium would equal 20 percent of the hospital's annual liability insurance bill.

-more-

In Stanford's case this would have added another $400,000 per year to its already very high premiums.

This alternative, said officials, was not accepted at Stanford because the hospital would have to charge the non-Medicare, and Medi-Cal patients significantly higher room rates for the 50 doctors who did not obtain insurance. Even after paying those rates, there would be still uninsured physicians on the staff.

Stanford hospital was notified recently that its malpractice premiums will cost nearly $2.4 million a year after a new rate hike becomes effective next month. The policy covers hospital and clinics personnel and the medical school faculty.

In August, 15 community physicians sought an injunction to prevent the hospital from requiring the insurance, and to prohibit the carrier from cancelling the hospital's insurance policy if uninsured doctors used the facility.

The court denied the request. Judge John M. Brenner, Santa Clara County Superior Court in Palo Alto, said, "that a doctor does not have the right to put a hospital in the position of having to pay the full cost of joint doctor-hospital negligence."

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos 415: 497-6911

STANFORD--Stanford University Medical Center, affected adversely by new Medicare regulations, has been notified by the Bureau of Health Insurance that it will be reclassified with the group of hospitals of the San Francisco-Oakland area.

The medical center would have faced a projected deficit of $4.5 million from the Medicare and Medi-Cal programs if its exception request to the BHI in Baltimore had been denied.

The problem, according to Clayton Rich, vice-president for medical affairs and dean of the School of Medicine, stemmed from new regulations that went into effect August 1.

The new rules established Medicare reimbursement ceilings, based, among other things, on geographic location of the hospital and per capita income of the area in which the hospital is located.

Stanford Medical Center was placed in a group of hospitals that takes in Santa Clara County with a maximum reimbursement of $97 per day for routine care, while it costs Stanford $140 per day to provide this care.

Stanford officials argued that the medical center was located 700 yards from the San Mateo county line, and costs and other economic factors coincided with those of comparable hospitals in the San Francisco-Oakland area than the rest of Santa Clara County.

Hospitals in San Mateo, San Francisco, Alameda, Marine and Contra Costa counties are placed in a group with a top reimbursement of $135 per day, and Stanford will now receive the same maximum level of reimbursement.

About 40 percent of Stanford's patients are Medicare and Medi-Cal beneficiaries. The new rules affect both programs.

The reclassification is not expected to eliminate the hospital deficit completely. The medical center still faces a deficit of more than half a million dollars from these programs.

Dr. Rich, however, indicated that the center would continue its present efforts to reduce costs through changes in organization of certain patient areas, and file requests for exceptional reimbursement where abnormal intensity of care required it. ###

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos 415· 497-6911

STANFORD--Dr. Frank J. Rauscher, Jr., director of the National Cancer Institute, and other noted speakers will highlight the dedication of the new $1.2 million Louis B. Mayer Cancer Biology Laboratory at Stanford University, Saturday, October 4.

Tours of the Department of Radiology and the new building will mark the beginning of the ceremonies at 10 a.m., which will conclude at noon with an address by Dr. Henry S. Kaplan, Maureen Lyles D'Ambrogio Professor of Radiology.

The new laboratory, located on Pasteur Drive and Governor's Lane near the medical center, will house a new program of cancer research under the direction of Dr. Kaplan.

Research in the building will involve an intensive attack on the basic aspects of human lymphomas, with respect to their biologic nature, immunologic behavior, and the increasingly strong possibility that they might be caused by viruses. Basic to these studies is the success Dr. Kaplan and his associates have had recently in cultivating in tissue culture the tumor cells from human malignant lymphomas.

Dr. Kaplan also plans to launch a program in experimental immunotherapy in collaboration with Dr. Michael Feldman, professor of cell biology at the Weizmann Institute of Science in Israel.

Dr. Feldman, who will join Stanford this fall during his sabbatical leave, has developed a technique for sensitizing normal human white cells in tissue culture to become killer cells.

A series of experiments are planned to determine whether these white cells of patients can be educated to recognize and attack the lymphoma cells in culture and to do the same thing when they are put back into the patient.

-more-

Another project will carry forward studies of the mechanisms underlying the development of very closely similar lymphomas in mice. The work had its beginning 18 years ago with the discovery and isolation by Dr. Kaplan of a leukemia-inducing virus in mice.

Completion of the Louis B. Mayer Cancer Biology Research Laboratory was made possible because of a combination of public and private funding. Support came from the National Cancer Institute, the Louis B. Mayer Foundation, the Friends of Radiology, and an anonymous gift through the San Francisco Foundation.

The building has been named in honor of the late Louis B. Mayer, a Russian immigrant whose interest in films began in 1908 and who served as vice-president and chief of production of MGM for 28 years.

The foundation that bears his name supports primarily medical education and research. It has been generous to the Stanford Medical School for many years.

Participants at the dedication will include Robert Minge Brown, president of the Stanford University Board of Trustees; Stanford University President Richard W. Lyman; Melvin C. Ury, chairman, Friends of Radiology Steering Committee; Dr. Clayton Rich, vice-president for medical affairs and dean of the School of Medicine; and Dr. Malcolm A. Bagshaw, chairman of the Department of Radiology.

The new laboratory contains about 11,000 gross square feet. It was designed with special consideration for containment of biohazards. A sophisticated heating, ventilating, and air-conditioning system handles exhaust air requirements of the laboratories in which virus work will be done. Tissue-culture and virus handling operations will be carried out in specially designed laminar-flow biohazard safety cabinets.

Architect for the project was the firm of Caudill, Rowlett and Scott of Houston, Texas. The Hodgson Construction Company of Redwood City was the general contractor, and Ray Rooker was the landscape architect.

FOR IMMEDIATE RELEASE

STANFORD —

Dr. Walter F. Ballinger, Bixby professor of surgery and head of the Department of Surgery at Washington University School of Medicine in St. Louis, Mo., will deliver the sixth Louis and Dorothy Kovitz Visiting Professorship lecture at Stanford on Wednesday, Oct. 8.

The professorship includes four days of doctors' conferences at Stanford and at Palo Alto Veterans Administration Hospital and Santa Clara Valley Medical Center.

Highlight of the visit will be Dr. Ballinger's discussion of "Experimental Transplantation of the Islets of Langerhans for the Control of Diabetes," 5 p.m. October 8, in Room M106 of the Medical School.

Physicians and other health professionals in the community are invited to attend the lecture.

The Kovitz Visiting Professorship was established in 1969 by Dr. and Mrs. Louis Kovitz of Los Altos to bring outstanding lecturers in medical and surgical fields to the Medical School.

Dr. Ballinger is well known for his work in hyperparathyroidism, as well as gastrointestinal physiology and metabolic responses to injury. A text *The Management of Trauma* which he coedited, is in wide use.

A graduate of the University of Pennsylvania School of Medicine in 1948, Ballinger has served at the Johns Hopkins University School of Medicine and as a consultant in surgery at Walter Reed Army Medical Center.

Currently, besides heading the Department of Surgery, he is surgeon in chief of Barnes and allied hospitals, consultant to the Jewish Hospital of St. Louis, Veterans Administration Hospital, and city and county hospitals in St. Louis.

He has held active committee posts with the American College of Surgeons, the American Surgical Association, and served for four years on the surgery training committee of the National Institute of General Medical Sciences.

STANFORD--A new program to train medical school faculty to teach general internal medicine will be established at Stanford University School of Medicine.

The program will be supported by a $180,000 grant from the Henry J. Kaiser Family Foundation of Palo Alto.

The two-year grant will be administered by Dr. Daniel D. Federman, Bloomfield professor and chairman of the Department of Medicine at Stanford.

Major emphasis of the program will be on preparing faculty for the teaching of general internal medicine. He cited "a severe shortage of well-trained junior faculty to exemplify and teach the role....

"It is clear that the academic pressures of the past 20 years have almost completely inhibited this source of faculty. The emphasis on subspecialization has oriented a whole generation of young internists away from academic careers based on practice, teaching and research in general medicine."

He continued, "Lacking this role model, students and house staff have abjured this direction. There is no greater need than for salary support of such faculty, enabling them to maintain their scholarly status by having sufficient time for teaching, learning, and research in addition to seeing patients."

The Kaiser grant will help support advanced fellowship training for selected residents interested in an academic career in general internal medicine. According to Federman, fellows would be "men and women who have completed three years of internship and residency in internal medicine, and are experienced in patient care, teaching, and research, preparing them to function as faculty." Federman expressed hope that a future program could provide basic training for residents preparing for practice.

Dr. Robert J. Glaser, president of the Henry J. Kaiser Family Foundation, noted in a letter announcing the grant, "Our trustees are aware of the dearth of well-qualified primary care physicians and the resulting need for a reemphasis on training in general medicine. They believe the fellowship program at Stanford...will offer a useful model and contribute toward remedying the situation."

EDITORS: The study on which this release is based is being reported Thursday, November 20, at the morning session of the American Heart Association meeting in Anaheim.

ADVANCE FOR RELEASE IN AFTERNOON PAPERS, THURSDAY, NOVEMBER 20.

STANFORD--People with sleep apnea--periodic breathing obstruction during sleep--have abnormal heart rhythms that can lead to death while they are asleep, a research team at Stanford University School of Medicine has found.

These irregular heart rhythms can be completely reversed, they reported.

The findings were presented Thursday, November 20, at the American Heart Association meeting in Anaheim, by Dr. Ara Tilkian, formerly of Stanford and now teaching at UCLA.

He worked at Stanford with Drs. Christian Guilleminault, John Schroeder, Kenneth Lehrman, and F. Blair Simmons.

The physicians studied and monitored 16 patients with sleep apnea. All patients had normal heart rhythms when they were awake, but showed a variety of rhythm abnormalities (arrhythmias) during sleep. Such arrhythmias are potentially dangerous and can lead to sudden death.

Eight patients had a tracheostomy--a surgical opening made to facilitate breathing at night. The opening was protected by an implanted valve which could be opened or closed by the patients.

The procedure eliminated the heart irregularities and also abolished the most common patient complaint of excessive daytime sleepiness.

Patients with sleep apnea stop breathing for periods of about 30 seconds as many as 400 or 500 times a night, explained Guilleminault in an interview. They tend to snore loudly when asleep and are sleepy during the day, probably because they have a disturbed sleep at night.

-- more --

22--Sleep

The condition was first described ten years ago in obese patients as Pickwickian syndrome. Then in 1972, physicians at the Stanford Sleep Disorders Clinic found that some insominia patients also had sleep apnea. Since patients with Pickwickian syndrome may have heart problems, they speculated at the time that sleep apnea may have associated cardiovascular abnormalities.

Sleep apnea occurs when the respiratory center in the brain that regulates breathing impulses malfunctions, or when a muscle weakness causes the upper airway (pharynx) to collapse, preventing oxygen from reaching the lungs.

A tracheostomy, which is an opening into the windpipe below the voice box, bypasses the obstructed airway and allows oxygen to pass into the system during sleep. It can be kept closed whenever the patient is awake.

When the valve was closed at night, all patients had the same arrhythmias they demonstrated before surgery. With the valve open so air could pass, the arrhythmias disappeared.

It is hoped that the restoration of normal breathing will lessen the chance of sudden death, said Tilkian and also prevent the development of other cardiac problems in such sleep apnea patients.

FOR IMMEDIATE RELEASE

STANFORD –

Stanford Medical Center's Division of Child Psychiatry has expanded its services recently, to include several new areas, including a special problems clinic.

A custody clinic has been established which accepts referrals of children involved in court cases. There is also a new crew of psychologists trained in developmental assessments.

The special clinic, according to Dr. Thomas F. Anders, director of child psychiatry, is directed at "problems that people don't pay much attention to, such as the depression associated with adolescent diabetes, or young children's nightmares. . . .

"There are areas that may require the multidisciplinary approach of a medical center, where we hope the community can use us as a resource. We hope that each special area will become a focus of research, and we will further improve our ability to help."

The division is building ties both with related Medical Center departments and with agencies in the community.

For example, recently a 16-year-old girl seen in the pediatric youth clinic was feeling "funny," and her epileptic mother worried that her daughter might have the same disease. She was referred to the new clinic, where it was found that the pressures of family, school, and emerging adolescence were the problem, rather than organic disease.

Anders has also revived a pediatric liaison program, in which he and child psychiatry residents attend pediatric conferences in the Stanford Hospital and are available for consultation with pediatricians on the ward.

The division is affiliated with several community agencies, including the Children's Health Council, Children's Hospital at Stanford, Peninsula Children's Center, and the Children and Adolescents Psychiatric Inpatient Service of San Jose Hospital.

Such affiliation proved helpful recently in the case of a six-months-old girl admitted to the Hospital pediatric ward because of vomiting. Pediatricians could find no organic disease. Upon referral to the special problems clinic, psychiatrists found that the mother had led a very stressful life, suffered a severe auto accident, became divorced, and had financial problems. Mother and child were referred to an affiliated program that specializes in helping mothers relate to their babies, as well as provide individual counseling for the mother.

The Division not only trains child psychiatry residents, but also pre- and postdoctoral clinical fellows train under Dr. Elizabeth Bing, chief psychologist and director of the Child Psychiatry Clinic.

The Child Psychiatry Clinic was founded in the 1930s by the late Dr. Hale S. Shirley, who pioneered in developing child psychiatry as a medical specialty. The clinic countinues to provide help in the more traditional problem areas of delinquency, runaways, drug-related cases, and problems with academic achievement, among many others. Referrals come from families, physicians, schools, or other agencies.

Anders became director of child psychiatry last year, having served as associate professor of psychiatry and pediatrics and director of the division of child psychiatry at State University of New York at Buffalo.

He received his A.B. from Stanford in 1956 and his M.D. in 1960. His research interests have been in the areas of community mental health services and the sleep patterns of infants.

ADVANCE FOR RELEASE IN AM PAPERS, THURSDAY, NOVEMBER 20, 1975

STANFORD--Medically supervised exercise programs for heart patients appear to be relatively safe according to a survey of programs in the U.S. and Canada.

Dr. William Haskell, physiologist at Stanford University Medical Center, presented the survey findings at the annual meeting of the American Heart Association on Wednesday, November 19, in Anaheim.

Coronary artery disease patients frequently are recommended a program of increased physical activity. The study was to determine the relative safety of such participation and the frequency of major cardiovascular complications during the exercise sessions.

Haskell reported that, based on current programs, the risk of death for cardiac patients while exercising in medically supervised programs is not much different than that reported for cardiac patients in general.

On the average, one death could be expected every 14.4 years of experience in current programs, based on 120 patients meeting three times a week. Only one death has occurred in programs surveyed since 1970.

According to Haskell, medical supervision is the key element for successful exercise training. "A medical evaluation and electrocardiogram should be required prior to the exercise," he says, "and a cardiovascular-trained nurse or physician should be in attendance who can give immediate care if necessary."

Another element of a successful, low-risk program is that it be designed individually for the patient by his physician.

Programs surveyed were required to include medical examination on entry and annually, and all sessions had to be medically supervised including the capability of providing electrical defibrillation and emergency medication.

Twenty-five programs meeting those criteria represented 86 exercise class locations in major population centers in the U.S. and Canada. Of the 25 programs, 24 did not perform continuous ECG monitoring of patients during the exercise session. The program that included such monitoring of all patients had no fatalities or cardiac arrests in 168,000 man hours of participation.

Haskell observed that "continuous ECG monitoring of patients may reduce cardiac arrest rate."

The survey also determined that a wide range of cardiovascular event rates occur among the programs, and most cardiac arrests are successfully resuscitated (82 percent).

Editors: This report is being presented during the morning session of the American Heart Association meeting in Anaheim.

ADVANCE FOR RELEASE IN AFTERNOON, WEDNESDAY, NOVEMBER 19.

STANFORD--Patients take too long to get to the hospital when they may have a heart attack, a Stanford University cardiovascular nurse researcher told the American Heart Association today, November 19, in Anaheim.

The biggest delay in getting a suspected heart attack patient to a coronary care unit occurs between the time a patient first experiences chest pain and the time he decides to seek medical help, Ms. Irene lamb told the group.

She reported the results of a recent study directed by cardiologist Dr. John S. Schroeder, assistant professor of medicine at Stanford. Two hundred and eleven patients with chest pain admitted to the coronary care unit of Stanford University Hospital were interviewed.

"The majority of deaths from cardiac disease occur outside the hospital, and as many as 30 percent of these seem to happen within an hour after chest pain begins," Schroeder said in an interview. It is essential that patients recognize oppressive pain or discomfort in the center of the chest as a possible heart attack and obtain proper care immediately.

He and Ms. Lamb found that 66 percent of the patients delayed more than three hours after they developed chest pain before reaching the hospital. Delays ranged from 10 minutes to three days.

Transportation only took 17 minutes on the average. Primary emphasis must be placed on patient education rather than on improved transportation for chest pain patients, Ms. Lamb said.

The advent of coronary care units in the 1960's dramatically improved the survival chances of heart disease patients, but they have to get to the hospital first, said Schroeder.

-more-

Nurses can play a greater role in the education of patients admitted to coronary care units, he noted. They can teach people to recognize the significance of chest pain, even those for whom heart attacks are ruled out after examination because this group is especially susceptible to a real attack with heart damage within a year, he explained.

Of the 211 patients studied, 61 had a heart attack on admission and another 30 developed one in the hospital. Preliminary followup showed that 15 percent of those for whom a heart attack was ruled out at the first admission were soon hospitalized with a real attack. Another 20 percent of the "rule outs" died within a year.

The researchers found that men delayed seeking help on the average of 30 minutes longer than women. Patients with previous heart attacks also delayed longer, "so hospitalization alone does not educate them," they said.

There were also delays in the emergency room and as a result of the study all chest pain patients are now monitored upon admission. The researchers suggest that emergency room personnel evaluate and transfer patients with chest pain to the coronary care unit as soon as possible.

STANFORD--A Federal rights panel has ruled that there is reasonable cause to believe Stanford University has violated provisions of the Civil Rights Act of 1964 by laying off a medical school black technician.

The finding was announced in a recent letter from Fred D. Brooks, Jr., acting director of the San Francisco District Office of the Equal Employment Opportunity Commission. (EEOC)

Brooks' letter invited the university and the employee to undergo conciliation efforts.

Douglas Barton, staff legal counsel for Stanford, said that an outside arbitrator, attorney Gerald Marcus of San Francisco, is scheduled to hear the case under an agreement between Stanford and the United Stanford Employees (USE), the union representing the technician.

The black man laid off as a medical school life-sciences technician is Roscoe (Rocky) McGill, a San Francisco resident.

McGill had charged that his attempted layoff in 1973, his suspension in 1974, and his permanent layoff in 1975 were all based on racial discrimination.

The EEOC found cause to believe only that McGill was discriminatorily denied cross-training in other skills which would have prevented his dismissal.

###

STANFORD--Stanford medical graduates will hold their annual fall reunion on the Stanford campus Friday, November 21.

Morning meetings will cover aspects of Stanford's work in orthopedic surgery in Room M106 of the Medical School.

Beginning at 9:35 a.m. the sessions will feature these topics:

"Problems of the Knee in Children" by Dr. Eugene E. Bleck, clinical associate professor of surgery; "Football Knee" by Dr. Frederick L. Behling of the Palo Alto Medical Clinic and clinical associate professor of surgery; "Dashboard Knee" by Dr. Donald A. Nagel, professor and head of the division of orthopedic surgery; and "Status of Total Knee Joint Replacement" by Dr. David J. Schurman, assistant professor of surgery.

The noon reception and luncheon will be in the Palo Alto Holiday Inn. Dr. Paul F. Basch, associate professor of Family, Community and Preventive Medicine, will speak on "Six Weeks in China: Recollections of a Barefoot Patient."

Other speakers include Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine, and Dr. Paul Campbell of Portland, Oregon, president of the medical alumni association.

ADVANCE FOR RELEASE IN AM PAPERS, THURSDAY, NOVEMBER 20, 1975

STANFORD--Mass media campaigns can help people eat right and stop smoking, lowering their risk of heart attack, according to preliminary results of a Stanford study in three Northern California communities.

Researchers cited a "rather large risk reduction" in two communities that received mass media campaigns in 1973 and 1974. Risk was calculated by measuring smoking, systolic blood pressure, plasma cholesterol levels, and relative weight.

They also reported dramatic changes in respondents' knowledge about heart disease risk factors.

Dr. John Farquhar, director of the Stanford Heart Disease Prevention Program, reported results from the second year of a three-year health education campaign on Wednesday, November 19, at the American Heart Association annual meeting in Anaheim.

Random samples of about 600 residents in Watsonville, Gilroy and Tracy are being monitored in the study. In Watsonville, radio, television, newspapers, billboards and mail focused on reducing smoking exercising, reducing weight, and consuming less cholesterol and saturated fat, but more polyunsaturated fat. In addition, a smaller group of respondents who were at high risk for heart disease received face-to-face personalized instruction from doctors, dietitians and other health personnel.

In Gilroy, the multimedia campaign was carried out, but not the personalized instruction. A random sample of residents of Tracy was surveyed each year as a control.

Data are still being collected in these communities during this third and last year of the study.

Farquhar reported that risk factors continued to be reduced in Wastonville and Gilroy subjects during the second year of the study. This was despite a reduced intensity in the media campaigning. Residents maintained or improved their behavior changes, said Farquhar, whereas Tracy residents showed the expected gradual rise in risk factors during the two year period.

Compared to no treatment, net risk reductions were 25 percent in Watsonville and 24 percent in Gilroy after two years of campaigning. First-year figures had been 21 percent reduction in Watsonville, and nearly 12 percent reduction in Gilroy.

-more-

Compared with control, systolic blood pressure dropped 6 to 9 percent in the two towns at the end of two years of campaigns.

Farquhar cited "impressive" results in getting people to reduce or stop smoking.

In Watsonville, 31 percent of high risk respondents had given up smoking by the end of the first year, and 44 percent by the end of the second year. Corresponding changes in Gilroy were 14.8 percent the first year and 13.1 percent the second year, and in Tracy 8.2 percent and 12.2 percent respectively.

Among the larger sample of respondents in each community, the net percentage of smokers changed most in Watsonville (18 percent), and less in Gilroy (6 percent) at the end of two years.

About 18 percent net fewer cigarettes were smoked by the Watsonville respondents the first year, and 22 percent fewer the second year. In Gilroy, there was no change the first year, and 5 percent fewer cigarettes smoked the second year.

The knowledge of smoking as a risk factor was significant in Gilroy, but did not seem to affect the individuals' behavior. Says Farquhar, "The implication is that stopping smoking is a complex matter, and the person needs feedback and individual instruction to accomplish it."

Data do indicate that sustained reduction in smoking can be achieved with a combination of mass media and face-to-face instruction, he added.

The researchers also found that knowledge changes surpassed behavioral changes. Says Farquhar, "Real changes occurred in risk factors. They persisted and were even extended in the second year. But there were even larger changes in knowledge. We saw that people can learn things, but not necessarily change their behavior."

He also noted, "We saw in addition that disadvantaged groups could increase their recognition of dietary risk factors at a greater rate than others in the communities. With carefully designed campaign programs, we might be able to close the 'knowledge gap' between the two groups."

The project is the first time that news media have been employed in an effort to change health habits at the community level, and the first attempt by scientists to evaluate whether or not the media can be used successfully for this purpose.

Dr. Farquhar heads the interdisciplinary research team. Dr. Nathan Maccoby, professor of communication, is co-principal investigator. Grant support is from the National Heart and Lung Institute.

STANFORD--A North American databank network designed to improve the care of thousands of arthritis patients has been established among eight medical centers in the U.S. and Canada.

The pilot project for ARAMIS (American Rheumatism Association Medical Information System) is being funded by an $854,000, three-year grant from the National Bureau for Health Services Research.

The project is under the direction of Dr. James F. Fries, assistant professor of medicine at Stanford University School of Medicine, with central computing facilities for ARAMIS at Stanford.

Fries believes ARAMIS will benefit both patients and physicians by making available to physicians information about a cross section of patients, including their ailments and treatment. ARAMIS will also tell physicians what has happened to the patients after they have received specific kinds of treatment.

Such a databank of information, Fries said, will provide for more accurate prognoses and therefore, more effective therapeutic programs. Databanks such as ARAMIS are not currently available to doctors on a nationwide, or international basis.

Fries said the project will also evaluate optimal ways of actually extending the system to many areas of the two countries.

In addition to Stanford, other medical centers participating in the ARAMIS network are the University of California at San Francisco, University of Cincinnati, Cornell, University of Pittsburgh, Phoenix Arthritis Center, UCLA and the University of Saskatchewan, Canada.

Fries said information on hundreds of patients with similar problems, as well as data on their treatment, will be pooled and analyzed by the computer.

As a result, Fries said, ARAMIS will be particularly beneficial to physicians dealing with unusual arthritic and rheumatic diseases.

Initial results show that successful treatment of rheumatic disease cases has "clearly increased," Fries noted. Furthermore, ARAMIS data shows that some patients should be receiving different kinds of treatment than those usually administered, he said.

As the project proceeds, Fries is hopeful ARAMIS will branch into a national databank system for rheumatic and other chronic diseases. He believes such a system could be developed within eight years.

Working directly with Fries at Stanford are associate director Dr. Alan Shapiro; Jean Porta, biostatistician; Alison Harlow and Jim Standish, information systems analysts; and, Cathy Williams, coordinating secretary.

STANFORD--Spinal arthritis may be more prevalent than previously suspected, according to Stanford University immunologists.

Over three million (Americans) may have undiagnosed, symptomatic ankylosing spondylitis, a type of spinal arthritis once considered rare, they say.

Drs. Andrei Calin and James Fries of the School of Medicine report their findings in the October 23 issue of The New England Journal of Medicine.

Ankylosing spondylitis, characterized by back pain, stiffness and inflammation, limits movement and can result in fusion of the spine. People with a certain hereditary antigen called W27 are known to be particularly susceptible to the disease.

Antigens stimulate the immune system to help fight disease. W27 belongs to a group of more than 30 antigens that determine how an individual responds to foreign substances and influence the acceptance or rejection of organ transplants. Every individual inherits four of these antigens--two from each parent--which are located on the surface of all body tissues.

About seven percent of the American white population, and a smaller percentage of the black population carry the W27 antigen. On the basis of former estimates of the incidence of ankylosing spondylitis, the investigators expected that some 2 percent of the men, and 10 times fewer women with W27 in any study would have the disease.

Yet they found a much higher frequency of up to 20 percent.

A detailed medical questionnaire was sent to 78 W27 carriers presumed healthy and 126 others who lacked the antigen. X rays were then taken of those the physicians thought might have the disease.

The X rays confirmed ankylosing spondylitis in eight of the 48 women and six of the 30 men who carried the W27 antigen. Twenty-seven non-carriers in the control group had normal X rays.

"Extrapolation of these figures to the United States population suggests that 20 percent of (those) who are W27 positive are affected," the authors write.

Although the disease may be more severe in men, nearly as many women may be affected, they suggest. However, women may not be so readily identified because of the reluctance to expose the female pelvic area to radiation.

The W27 antigen serves as a helpful genetic marker to screen for ankylosing spondylitis in patients with a history suggesting inflammatory backpain. Since there are drugs which effectively control the painful symptoms of the disease, the report concludes, "increased awareness of ankylosing spondylitis may result in substantial clinical benefit to large numbers of patients."

Their work was supported in part by the Arthritis Foundation. ###

SCIENCE WRITERS: The scientific paper on which this story is based will be presented Thursday, November 6, during the morning meeting of the Acoustical Society of America in the Jack Tar Hotel in San Francisco.

ADVANCE FOR RELEASE IN AFTERNOON NEWSPAPERS, THURSDAY, NOVEMBER 6, 1975.

STANFORD –

An important discovery, believed to bridge a major evolutionary gap between man and animals, was reported Thursday, Nov. 6, by a Stanford University scientist.

Dr. James H. Dewson, III, told the meeting of the Acoustical Society of America in San Francisco that monkeys have now been shown to possess a type of brain which earlier had been associated primarily with man's specific intellectual capacities.

In humans there is an asymmetry of brain organization, and each half of the brain, therefore, is specialized to handle different activities. The left hemisphere deals particularly with those activities which contribute to the understanding and use of spoken language.

Dewson said that like humans, monkeys have been found to have similar asymmetries of brain function.

Researchers have generally determined, Dewson explained in an interview, that monkeys had brains with two operationally equal halves. Animals certainly exhibit no natural linguistic behaviors similar to man's which might demand one-sided brain specializations.

"It is also possible, however, that the underlying complex brain functions ultimately necessary for man's language have not been thoroughly examined in animals," he noted.

Hoping for clues to the reasons for asymmetry of human brain functions, Dewson and his associates turned to man's evolutionary past—the monkeys. Under grants from the National Science Foundation they trained more than a dozen macaque monkeys to recognize various sounds and to match these sounds with certain colors. The task demands not only listening and looking but a form of recall memory as aell.

To obtain their food pellets, the monkeys were taught to listen to a sound from a loudspeaker on a panel resembling a slot machine.

The particular type of sound could never be predicted ahead of time by the monkeys. After hearing it, they had to decide which of two lighted buttons, one red and one green, was correct according to the sound they had just heard.

If they pressed the correct colored button, it rhowed they remembered the sound.

(more)

After the animals learned this task perfectly, Dewson introduced delays between the end of the sound and the lighting of the random-position color buttons. As the monkeys experienced progressively greater difficulty in remembering a sound, their memory capacity was plotted on a chart.

Having shown that by this method the monkeys could remember a sound for as long as 20 seconds, Dewson and his colleagues surgically removed a part of the brain called the auditory association cortex.

This part of the monkey's brain may correspond to a part of the left side of the human's brain where many so-called language functions seem to be located.

"We performed this operation six times," Dewson said, "and without any question, without any overlap, all of the animals with damage to the left side had their auditory recent memory capacity virtually wiped out."

Two animals whose brains were damaged on the right side did not show any deficient memory, he added.

"It seems that unevenness of function between the two hemispheres of the brain is not restricted to humans," Dewson said, "and it cannot possibly be linked exclusively to man's linguistic behavior."

Dewson said that the trained monkeys can be used as an animal model for studies of such maladies as strokes which lead in humans to aphasia or loss of the capacity for understanding or expressing thoughts conveyed by language.

"These monkeys can also be helpful in studies which seek clues to the evolution of man's intellectual prowess," he explained.

In recent years apes have been taught to communicate with people either through sign language or appropriate use of plastic symbols or computerized visual displays, he said. These experiments demonstrate that nonhuman primates are capable of much more complicated thinking than had previously been supposed.

"Monkeys, as well as apes, can now provide us with vital and unexpected information about the organization of the human brain," Dewson said.

Dewson heads the Hearing and Speech Sciences Section in the Division of Otolaryngology. His report was coauthored by Allen C. Burlingame, Kenneth Kizer, Sue Dewson, and Patti Kenney, all research assistants, and Dr. Karl H. Pribram, professor of psychiatry and psychology.

STANFORD--Stanford University School of Medicine's new department of neurobiology has been awarded $270,000 for research and training from the Alfred P. Sloan Foundation of New York.

The grant, effective November 1, was announced Monday, November 3, by Dr. Clayton Rich, vice president for medical affairs and dean of the medical school.

It is part of the Sloan Foundation's program to support new developments in the neurosciences.

Dr. Eric Shooter, professor and chairman of neurobiology, said the award will help the department get started over the next three years while additional funding is being sought from other sources. The money will be used toward faculty salaries, graduate student support, equipment and materials.

The neurobiology department was established last month to coordinate training and research related to the brain and nervous system in the medical school. With the new department, teaching and scientific activities in the basic neurosciences are being expanded.

STANFORD--Discovery of three types of sleep apnea and their possible relationship to the mysterious sudden infant death syndrome or "crib death" has been reported recently by Stanford University medical researchers.

Apnea is a condition marked by the temporary cessation of breathing during sleep. In the last three years, sleep researchers have gathered a mounting body of evidence that crib death may be caused by defects in the mechanism that controls breathing.

Drs. Christian Guilleminault and William Dement in collaboration with Dr. Rose Peraita and Mariane Souquet studied 15 premature infants and eight full-term babies in the Stanford hospital nurseries.

The preemies, they reported in the journal Science, suffered apneic episodes after birth. The full-term babies had been taken to the emergency room or to their pediatricians to be treated for "stop-breathing" episodes during sleep.

These episodes were treated by stimulation ranging from shaking the baby to mouth-to-mouth resuscitation. When they were discovered having difficulty breathing, the babies were described by their parents as "white," or "unconscious," and "not breathing."

The babies were given complete pediatric examinations, but these failed to explain the sudden loss of consciousness during sleep. The only exception were five infants who had respiratory infections when hospitalized.

The babies were studied during sleep and wakefulness for several weeks. The studies included polygraphic recordings of their brain waves, heart and respiration monitoring, and behavioral observations by a specialist stationed in the nursery.

Guilleminault and Dement found three types of apnea in both groups of infants.

One type, central or diaphragmatic apnea, involves no movements of the respiratory muscles of the abdomen and chest. In upper airway apnea, the diaphragm moves but there is no exchange of air because of an obstruction at the top of the windpipe. In mixed apnea, a period of upper airway apnea follows one of central apnea.

The Stanford researchers believe these distinctions are important.

The heart rate of normal people slows when they hold their breath. This is the "diving reflex." Dement and Guilleminault found that a similar slowing of the heart rate occurs in infants during all three types of apnea but that it is more severe during episodes of the upper airway and mixed types.

-more-

Moreover, they have measured a greater loss of oxygen from the blood during these two kinds of apnea than during central apnea.

They have also observed frequent heart beat abnormalities during upper airway and mixed apneas.

Preemies with relatively high birth weights, and "near-miss" infants, that is, those who were found in time and resuscitated, have all three kinds of apnea, according to the researchers. But preemies with very low birth weights have predominantly central apneas.

Guilleminault and Dement suggest that certain infants may have a slight regulatory defect of the central mechanism of respiration during sleep. Mild upper respiratory infections in such infants may cause upper airway apnea, heart rhythm abnormalities, and, in some instances, death.

The Stanford researchers recommend hospitalization and careful evaluation when an upper airway infection occurs in infants with previous history of "stop-breathing" episodes.

The new findings are far from providing a complete answer to the riddle of crib death. But the researchers believe it is an important step in understanding a condition which, in the United States alone, kills up to 18,000 infants every year, and is the leading cause of death between the ages of 1 and 12 months.

The research was supported by grants from the National Institute of Child Health and Development of the National Institutes of Health.

STANFORD--In the spirit of the season, doctors and nurses on the Delivery Room staff at Stanford University Hospital are planning to make this Christmas a little brighter for a group of area senior citizens

For the fourth straight year, the staff is shelving its past tradition of office exchange gifts. Instead, the staff is pooling its resources to purchase gifts and some commodities for the elderly living in a Mountain View retirement home.

"As in the past, the nurses are spearheading this themselves," explained Delivery Room Head Nurse Barbara Petree. "It is something we all thoroughly enjoy. It really gets us into the Christmas spirit."

The nurses decided to help the elderly when it was learned recently that three of them have no families to share the season with. Since then the Christmas project has been taken over by staff nurses Gwen Anderson, Marie Smith and Biruta Cavara, who have made arrangements to have the Christmas packages delivered to the home.

Although the project seems to develop spontaneously each year, not everyone on the Stanford staff is a volunteer donor.

"Some of our doctors are sort of conned into it," Mrs. Petree noted with a grin. "One doctor was approached and he turned his pockets out and said, 'look, I'm broke.' The nurses replied, 'hey, that's okay. How much would you like us to put you down for?' "

Four years ago when the Delivery Room staff hit upon the idea of helping needy families they agreed to take care of a Half Moon Bay mother and her 12 children.

"We discovered her children had never had new Christmas presents," Mrs. Petree said, "so that was all the incentive we needed to help them. But, in addition to the presents, we also gathered food and clothing for them. Everything took up the whole back of a station wagon."

The following year the staff donated gifts to a convalescent home and last year they played Santa Claus for a family of six in Mountain View that had been on a string of bad luck.

"The mother had a number of medical problems and the family was barely making it, nevertheless they were too proud to go on welfare," Mrs. Petree noted. "And to top it off, their home was burglarized just before Christmas."

At first, she said, the family was reluctant to accept the food, clothing and presents but they eventually changed their minds.

"The family came in later to thank us. Each of the children had signed a thank you letter. We didn't expect this kind of praise. It was very touching." ###

STANFORD--Dr. Edward L. Ginzton, chairman of the board of Varian Associates of Palo Alto, and Kenneth R. Hansen, a consulting economist in Los Altos, have been named to the board of directors of Stanford University Hospital.

The new members were appointed by the University board of trustees on December 9.

Dr. Ginzton, who received his Ph.D. in electrical engineering from Stanford, served as a professor of applied physics and electrical engineering from 1946 to 1968. He then became a founder of Varian Associates. He is a member of the National Academy of Sciences, the National Academy of Engineering, and the American Academy of Arts and Sciences. He is a fellow of the Institute of Electronic Engineers, and is a member of the advisory committee of the School of Engineering.

Hansen is a consulting economist who specialized in economic analysis of investment opportunities, national and international financial planning and organization of public and private institutions, and systems analysis. He is a fellow of the Adlai Stevenson Institute in Chicago, and an advisor to the United Nations and to the inter-American Development Bank.

Others on the Hospital board are Frank H. Roberts, an attorney with the firm of Pillsbury, Madison and Sutro of San Francisco; Dr. Alejandro Zaffaroni, president of Alza Corporation of Palo Alto; John M. Santana, Jr., vice president of Peninsula Creamery Company; Conrad F. Gullixson, an attorney with Lakin, Spears of Palo Alto; Mrs. O. Meredith Wilson of Palo Alto; Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine; and Carroll J. Roush, chairman of Rocor International, Palo Alto.

###

STANFORD--"As Life Begins," an hour-long special television program about the mysteries that surround human life from its conception to birth will be shown at 10 p.m., Monday, December 22, on KGO-TV (Channel 7).

The show utilizes the knowledge of over 18 medical specialists in neonatology, genetics, immunology, birth defects, and obstetrics. Several Bay Area institutions are represented.

Among those interviewed on the show from Stanford University School of Medicine are Dr. Howard Cann, pediatric geneticist; James Schroder, cytogeneticist; and Michael Iverson, immunologist.

The program also will analyze the present level of research in such genetic diseases as sickle-cell anemia which affects only Blacks; tay sachs disease which affects only Jews; thalassemia which affects people of Mediterranean origin, and cystic fibrosis affecting only Caucasian children.

The program was produced and written by Roger Herst and Bob Anderson of KGO.

STANFORD--An independent arbitrator has upheld the 1974 suspension of a Stanford University medical school black technician.

Roscoe (Rocky) McGill, a medical school life sciences technician, had charged that his suspension had been based on racial discrimination.

Arbitrator Louis Garcia of San Francisco, former commissioner of the Fair Employment Practices Commission, heard the case under an agreement between Stanford and the United Stanford Employees (USE), the union representing the technician.

Garcia affirmed the suspension without pay, and found that the discipline "was not the result of sexism, racism, or past union activities of grievant."

McGill has also charged that an attempted layoff in 1973 and a permanent layoff in 1975 were based on racial discrimination. A second arbitration is pending regarding that layoff.

Earlier, in a separate action the Equal Employment Opportunity Commission (EEOC) ruled that there is reasonable cause to believe that the University violated provisions of the Civil Rights Act of 1964 in denying McGill cross-training in other skills which would have prevented his dismissal. The panel invited the University and the employee to undergo conciliation efforts.

According to Douglas Barton, staff legal counsel for Stanford, the EEOC has now advised the University to abandon those conciliation efforts since McGill has recently filed suit against the University in U.S. District Court, charging racial discrimination.

STANFORD--Dr. Abraham J. Treves, an Israeli scientist, has joined the Stanford University School of Medicine's Department of Radiology as the first Naomi van den Horn-Adelson Research Scholar.

Dr. Treves will be studying the specific sensitization of human white cells against human lymphoma cells. He will be working under the direction of Professor Henry S Kaplan, director of the Cancer Biology Research Laboratory, and Dr. Michael Feldman, visiting professor from the Weizmann Institute of Science in Israel.

Dr. Feldman has developed a technique for sensitizing normal human white cells in tissue culture to become killer cells. Experiments are planned to determine whether these white cells of patients can recognize and attack the lymphoma cells.

Dr. Treves received his Ph.D in the Department of Cell Biology at the Weizmann Institute. His initial appointment at Stanford is for one year.

The Naomi van den Horn-Adelson Research Fund was established by Mr. and Mrs. David E Adelson of Berkeley, in memory of their daughter who died of Hodgkin's disease in 1970. Support is designated for young physicians and researchers studying human malignant lymphomas.

FOR IMMEDIATE RELEASE

EDITORS: Review copies of the book are available at the Stanford Medical Center News Bureau.

Ian, a 27-year old Army veteran, had a history of drug abuse since he was 17. He did not use heroin until he was drafted and served in Vietnam where the stuff had been widely available at $2 a fix.

When he was discharged and returned home, Ian was sick and felt lost. He joined the Marines but he was unable to kick the habit and was discharged.

Ian was one of many thousands of veterans "addicted in action" in Vietnam, who needed help desperately. Fortunately, he was lucky enough to get into an innovative program at Palo Alto Veterans Administration Hospital which offered him a chance to return to normal life.

He now lives in an apartment in the community and attends college regularly. His dependence on drugs has been eliminated.

Ian's success story and of the program that helped him and other Vietnam war heroin addicts are described in a new book, *Drug Addicts in a Therapeutic Community: The Satori Approach* (257 pp. cloth $14.50, York Press, Baltimore).

The book is authored by Dr. Vincent P. Zarcone, Jr., a senior attending physician in the Department of Psychiatry and Behavioral Sciences at the Stanford University School of Medicine. It shows how the program evolved, describes the lessons learned along the way, and offers guidelines for setting up similar programs at other centers.

The program, called Satori and meaning enlightenment, was started experimentally at the Veterans Hospital in 1971 by a group of Stanford psychiatry professors.

Treatment in Satori is similar to that of medical illness in a hospital. It is in three phases that last 16 to 28 weeks. A patient enters treatment, is treated, and then leaves.

"This is one major difference between Satori and Synanon-type programs in which treatment of finite duration is not a goal," explained Zarcone.

In the Synanon system, addicts are trained to live within an alternative life-style and then are expected to stay.

"We feel it is unwise to seek this goal because it results in people who live on the edge of the general community," Zarcone said. "Ever since the Middle Ages, Western culture has tended to keep various groups—lepers, the very poor, the mentally ill-just outside the city walls.

"For us, such an attitude is impossible. We set as our goal the return of a productive, coping member of society to the general community beyond the hospital."

The program uses concepts developed in therapeutic communities for psychiatric patients. They include encounter groups, and other forms of therapy which force a man to face his addiction and admit to himself whatever it is he has been trying to evade.

Therapy usually starts with methadone detoxification. But unlike traditional methadone maintenance programs that tend to substitute one addiction for another, the Satori approach at the Veterans Hospital uses methadone only to buy time.

"We believe that social psychiatric intervention is more important and that methadone maintenance is not a solution by itself," said Zarcone.

The result: as many as 70% of the addicts that leave the Palo Alto VA Hospital program are less likely to be using heroin at one year, less likely to be arrested or convicted, and more likely to be working or attending school than patients who were not treated or stayed in the program for a short time.

The research also indicates that length of stay in the program is highly related to a change in life-style as measured by abstinence from heroin, work history, and lack of criminal activity, Zarcone said.

Of those who were discharged after at least six weeks in the program, only 46% continued on methadone after the end of the first-year study.

(more) 12/1/75

The outcome, however, should be interpreted with caution, Zarcone notes, because the figures come only from one year's study. Reports from two-year interviews now being conducted will present a more accurate comparative picture of results.

Zarcone describes the program as a complex therapeutic community. "This means we use a combination of social pressure to persuade people to change their ways of relating to others, individual and group psychotherapy, and psychoactive drugs.

"Satori involves patients in real relationships. Most therapeutic communities maintain well-defined healer-patient roles while Satori is a brotherhood or family."

Patients enter the program after a screening meeting with the staff and senior patients. Candidates sign a probationary admission contract and become aware that they will have to control their behavior in many areas in order to move through the phases of the program and graduate successfully.

Once they have passed the motivation test, the patients become members of the self-governing therapeutic community.

"We try to be frank about the nature of the program and its goals," Zarcone said.

The brochure which the Palo Alto VA Hospital distributes to prospective patients reads in part:

"The program is a small, tight community of veterans who want to kick drugs. It has three goals: Clean up, get your head on straight, and learn to live in the real world.

"It is tough for a drug abuser to reach these goals. You have to be out front with your feelings and behavior or you won't make it. Secretiveness, holding it in, and keeping to yourself insure failure. . . .Until your brother shares his secret he has no safety from it . . . . So people in the program help each other—really help.

"The clean-up part of the program takes at least two weeks. You are on probation and restricted to the immediate living area. Your motivation and capacity for change are being tested. Methadone may be used to help with withdrawal symptoms.

"Getting your head on straight means understanding your emotional problem—why you have to be loaded to make it through the day. In small group raps, you learn to see yourself through others' eyes.

"Learning to live in the real world means acting on what you learn in a small group . . . . It may mean developing new friends, cleaning up sick relationships, and making plans to do your thing. . .or learning what it is."

The new program at the Palo Alto VA Hospital spends about $2,500 to treat one patient. "This seems inordinately expensive to some people," Zarcone said. "But these figures are not high in comparison with the more than $350 million that the narcotics traffic is estimated to cost U.S. society."

Costs are attributed, in part, to the large staff-patient ratio. Most, if not all, of the nursing assistants have been either trained in psychology or have bachelor's degrees in that subject. Also a large number of people, including physicians, social workers and nurses work there part time.

Zarcone believes that therapeutic communities of this type will need to be developed to take care of the influx of veteran addicts.

"It takes about three to four years on the street," he said, "before a person becomes motivated to seek help. This group probably will not begin to arrive in large numbers for treatment until the latter part of the seventies."

In a foreword to the book, California Senator Alan Cranston writes that the Satori approach "has stood the test of experience to become a viable drug treatment alternative."

"It provides the basis for a model, which can, and I hope, will be replicated in other medical centers," he adds.

STANFORD--Vigorous physical activity, like running, swimming and cycling, not only improves the functioning of the heart and muscles, but also lowers blood fat and cholesterol, wards off constipation and hemorrhoids, and may even help in the fight against cancer, says a Stanford researcher.

Speaking at the National Track and Field Coaches Clinic at Rickey's Hyatt House in Palo Alto Saturday (January 31), Dr. Peter D. Wood, deputy director of the Stanford Heart Disease Prevention Program, outlined the physiological effects now known about vigorous exercise.

He addressed almost 400 coaches and athletes who had gathered to discuss training techniques and tactics. Dr. Wood noted that "physical educators must now consider what participation in vigorous sports has to offer to the large numbers of people who are not destined to be champions."

Muscle mass increases and body fat decreases as a result of vigorous exercise, he said. Women runners, though they have a greater body fat content than active men, still have a much lower fat level than inactive women.

Wood's research has confirmed that blood cholesterol in runners is somewhat lower than in more sedentary people, and also that the distribution of this cholesterol "is very favorable in runners."

A recent Stanford study has found that triglyceride levels, or levels of blood-fat, are remarkably low in groups of male runners aged 30 to 60, about one-half the level in more sedentary men.

Women runners were even lower in this respect than the male runners. He pointed out that women runners have more body fat than male runners, but lower levels of fat (triglyceride) in the blood.

The heart enlarges with exercise, "but in a healthy way," says Wood, "to become a bigger, more powerful pump. The resting heart rate slows; stroke volume increases; heart cells develop more mitochondria."

Mitochondria are particles inside cells which contain enzymes. Increased mitochondria increase the capacity of the cells to contract.

222--Exercise Benefits

Blood pressure falls following vigorous exercise. "Generally very active people have relatively low pressures," says the researcher, "although the value of exercise in reducing elevated blood pressure is still not clear."

Does running help prevent cancer? "It sounds rather revolutionary, but the answer is almost certainly yes," says Wood, "because runners almost never smoke. According to the Surgeon General's reports, smokers suffer considerably more than non-smokers from several forms of cancer, not only lung cancer," says Wood.

In his research, Wood has found that "for reasons not entirely clear, smokers who become runners always quit smoking."

As another benefit, he cited that "vigorous activity seems to promote regularity.... If this is true very active people probably enjoy relative freedom from hemorrhoids, varicose veins and intestinal disorders in later life."

Wood told the gathered coaches that they can not only give their students the opportunity for recording-breaking performances in early life, but with lasting involvement in exercise, possible protection from disease in later life.

"A person who is in this well-conditioned state is much better able to withstand abrupt physiological insults, like an injury or sudden illness," he said.

Wood, adjunct professor of medicine at Stanford, is also considered one of the finest senior distance runners in the country.

STANFORD--Dr. William H. Northway Jr., associate professor of radiology and pediatrics, has been appointed director of the Diagnostic Division and associate chairman of the Department of Radiology at Stanford University School of Medicine.

Northway succeeds Dr. F. Frank Zboralske, professor of radiology, who will continue to do research in the department, according to Dr. Malcolm Bagshaw, chairman of the Department of Radiology.

A graduate of Stanford with a B.A. in 1954, Northway also received his M.D. from Stanford in 1957. He interned at New York Hospital (Cornell University) and completed his radiology residency at Stanford in 1961.

Northway was a James Picker Foundation Scholar in Radiology in 1963-66, and a resident étranger at hopital des Enfants Malades in Paris in 1963. In 1965-66 he was voted the best pediatric instructor by the pediatric resident staff. He was also a Stanford University Fellow in 1972-75.

Northway has concentrated his research in the area of newborn lung disease, and particularly in pulmonary oxygen toxicity in newborn infants. He has written numerous medical articles and book chapters.

STANFORD--New visiting hours will be from 11 a.m. to 8 p.m. daily in the general care units of Stanford University Hospital.

The new hours, modified in order to better provide rest and quiet for patients and enable Hospital staff to provide timely and effective care, were approved recently by the Medical Board. Previously, visiting hours had extended from early morning until 9 p.m.

As in the past, state law provides that children under 16 may not visit in the maternity department or maternity lobby. This age restriction has now been extended to the nursing unit adjacent to the maternity area and to other units with patients receiving immuno-suppressant drugs.

Children under 12 years may not visit, and no more than two visitors per patient are normally permitted.

The new hours and age restrictions are posted at the entrance to each nursing unit.

Maternity visiting hours remain the same: 3 to 4:30 p.m. and 7 to 8:30 p.m., with infants being shown at these hours only. Fathers may visit at any time.

In pediatrics, parents may visit their children at any time. No visitors under 16 years of age are permitted.

Visiting hours in the intensive and respiratory intensive care units remain 10:15 to 10:30 a.m., 1:15 to 1:30 p.m., 5:15 to 5:30 p.m., and 7:45 to 8 p.m. Only the immediate family and members of the clergy may visit at these times. All visits are at the discretion of the nurse in charge.

In the coronary care unit, immediate family and members of the clergy may visit for 10 minutes out of each hour at the discretion of the nurse in charge.

In the therapeutic community at Hoover Pavilion, visiting hours are noon to midnight. There is no age limit. Visits may be limited at the discretion of the physician or nurse in charge.

Visitors to both the main center and Hoover Pavilion are urged to observe posted "no smoking" signs. Smoking is permitted only in designated areas.

FOR IMMEDIATE RELEASE

STANFORD –

Dr. Leonard Hayflick, professor of medical microbiology, has resigned from the Stanford University faculty effective immediately, it was announced Friday, February 27.

Hayflick's resignation stems from a dispute between the 48-year old scholar and the University over the management of certain University research contracts.

Hayflick maintains that he managed the contracts in compliance with the University's and contractual guidelines.

Stanford was concerned that its laboratories were inappropriately used in the performance of a contract to store, produce and distribute a strain of human cells, some of which Hayflick sold on his own behalf.

In addition, Hayflick was told that he improperly deposited fees received for mycoplasma testing into a non-University bank account for his personal use.

John J. Schwartz, assistant vice-president and counsel for medical affairs, said the University initiated a study last June after receiving inquiries from government contract officials concerning Hayflick.

He added that the University will seek recovery from Hayflick of the $9,500 in testing fees that should have been deposited to University accounts.

Hayflick maintains that the collection of fees was done openly for the past seven years and with the knowledge and consent of contract officers.

He said that the establishment of the non-University account was the result of misinformation received by Hayflick when he inquired of University policy.

He denied that the funds were deposited for his personal use.

Hayflick said that, in fact, he first initiated the inquiry himself by contacting government officials to clarify contractual policies and procedures, which he felt were still unclear, although long established.

Hayflick joined Stanford as a professor of microbiology in 1968.

He is credited with discovering that cultured normal human cells from embryonic connective tissue (known as fibroblasts) subdivide 50 times, then die out.

He also has advanced the theory that cells gradually acquire errors in their genetic information and their "program" is played out, resulting in aging and an ultimate limit to the span of life.

Hayflick urged for a number of years that the cell strain he developed be used as a medium for safer vaccine production.

As a result of his efforts, a license was issued in 1972 by the Division of Biologics Standards (now a part of the Food and Drug Administration) to produce an oral, live-virus polio vaccine cultivated on human cells.

Hayflick also established a cancer virus research program at Stanford in 1968.

He received his Ph.D. from the University of Pennsylvania.

His work has received awards from the National Cancer Institute, the Gerontological Society, and the Southern California Gerontology Center.

STANFORD--The National Labor Relations Board's General Counsel says it has authorized issuing of a complaint against Stanford University and Stanford University Hospital alleging the Hospital unlawfully assisted two minority employee groups active in affirmative action efforts.

The allegation says that the Hospital acted unlawfully by providing assistance such as meeting rooms, time off to attend meetings, some materials and supplies and occasional advice by certain administrators

The complaint is a result of charges of unfair labor practices during a labor election campaign last April. Charges were filed by United Stanford Employees (USE) Local 680, of the Service Employees' International Union, on April 9, 1975.

USE had alleged that the Alianza Latina and the Black Advisory Council were dominated and controlled by the Hospital administration, and had campaigned as agents of the administration in urging employees to vote against representation by USE. In the election, employees had rejected representation by overwhelming majorities.

According to supervisory examiner Dean Francis of the San Francisco Regional Office of the NLRB, the Counsel rejected the USE allegation that the groups were dominated by the administration or agents of it.

The Counsel alleged that the two minority employee groups are "labor organizations," a legal term for labor unions.

The Hospital and University have contended that neither group should be considered a labor organization since they had been organized as part of a nation-wide recognition of the needs of minority employees. Hospital officials say that neither group regards itself as a labor union, and each provides advice to the Hospital about improving affirmative action programs and relations with minority employees.

The Counsel action does not mean final decision by the NLRB. The matter will now be heard by an administrative law judge before a decision is made by the Board.

Under the law, the Counsel issues a complaint when a case involves novel issues which it feels should be decided by the Board, since Counsel decisions cannot be appealed.

To date, the NLRB has not yet ruled on the labor organization status of employee groups involved in civil rights and affirmative action.

STANFORD--A recent Stanford study reports that women who use oral contraceptives or older women who take estrogen-only compounds are at greater risk for heart disease than women who do not use the "pill."

Researchers found that women taking birth control pills that contained a combination of estrogen and progestagen hormones had increased blood pressure as well as increased levels of triglycerides, a type of blood fat recognized as a factor in risk for heart disease.

They also found that estrogen-only pills generally caused a rise in triglycerides, but had little effect on blood pressure. Estrogen-only pills are more likely to be taken by post-menopausal women.

The study is based on 986 randomly selected women, age 35 to 59, in the Northern California communities of Watsonville, Gilroy and Tracy. The research was conducted as part of the three-year study of heart risk factors in those communities

The report was published in the current issue of the Journal of the American Medical Association, and authored by Dr. Michael P. Stern, Dr. Byron W. Brown, Jr., Dr. William L. Haskell, Dr. John W. Farquhar, Clare L. Wehrle, and Dr. Peter D.S. Wood, all of the Stanford Heart Disease Prevention Program.

According to Dr. Stern, the project did not try to detect actual heart disease, but rather changes in factors, blood pressure and triglycerides, that are thought to increase the risk of heart disease.

The report supports an early widely publicized study by the Royal College of General Practitioners in London in 1974 that found that women taking oral contraceptives were two to two-and-a-half times more likely to develop hypertension than those who do not take the medication.

The Stanford study reported differences in risk factors somewhat greater than those reported by others. Average systolic blood pressure was 7.2 mm higher among users compared with non-users.

-more-

Higher triglyceride levels were found among those taking estrogen-only (19.9 milligrams percent increase), and among those taking the oral contraceptives (75.8 milligrams percent increase).

Although the results suggest that effects are greater with oral contraceptives than with pure estrogens, Dr. Stern emphasizes that this does not mean that estrogen-only medications are "safer" than oral contraceptives.

Stern noted that estrogen-only pills are generally taken by women in the older age range who may be more vulnerable to heart attacks. Stern noted the serious lack of information about the effects of pure estrogen, and the need for more studies in this area.

In the study, women were divided into Mexican-American and "other white" categories to detect if there were ethnic differences in risk factors.

The study noted "an apparently greater susceptability of Mexican-American women to the blood pressure effects of oral contraceptive use." Among the Mexican-American women, systolic blood pressure was 19.9 mm higher and diastolic pressure 9.4 higher in users of oral contraceptives than in non-users.

Stern suggested that the greater increase may be because the Mexican-American women tended to have higher weight levels.

The researchers termed it "paradoxical" that female hormones should increase heart attack risk when women generally have a lower heart attack rate than men. Stern cited possible "yet undiscovered differences in metabolic effects between the natural female hormonal cycle and the artificial one produced by hormone administration."

The Stanford study is supported by grants from the Lipid Research Clinics Program of the National Heart and Lung Institute, and from a gift of CPC International.

STANFORD –

Paul B. Hofmann, director of Stanford University Hospital and Clinics, has been presented the Robert S. Hudgens Memorial Award of the American College of Hospital Administrators as the outstanding "young hospital administrator of the year."

The award was presented to Hofmann during a meeting of the ACHA in Chicago Feb. 19.

Named after a former director of the graduate program at Virginia Commonwealth University in Richmond, VA, the Hudgens Award is given in cooperation with the Alumni Association of the Department of Hospital and Health Administration at the university.

The American College of Hospital Administrators is a professional society of 11,500 health care executives. It offers continous education for administrators in the health field for improving management in hospitals, clinics, and other health service institutions.

Hofmann, 34, was named director of Stanford Hospital and Clinics in 1974. Previous to that he was deputy director of the hospital.

Prior to his appointment at Stanford, Hofmann was associate administrator of San Antonio Community Hospital in Upland, CA, and a faculty member of the UCLA graduate program in hospital administration.

Previous appointments included 2½ years at Massachusetts General Hospital in Boston as research associate and assistant director of the Laboratory of Computer Science, during which time he was on the faculty of the Harvard School of Public Health.

Hofmann is a fellow of the American College of Hospital Administrators, chairman of the American Hospital Association's Council on Research and Development, and a member of several state and local health committees.

STANFORD--A Stanford radiologist foresees wide-scale abdominal screening of patients by means of high-speed "sound pictures."

New ultrasonic equipment can produce continuous moving images as on a television screen.

Dr. Jason Birnholz, assistant professor of radiology at Stanford, is working closely with Stanford's birth defects clinic and the Department of Obstetrics and Gynecology to monitor fetal growth by means of ultrasound. He is also studying tumors with the division of radiation oncology.

A current line of research is aimed primarily at the prenatal detection of fetal abnormalities with ultrasound, particularly in families at high risk for genetic disease or congenital malformations.

In a more routine application, new ultrasound equipment is being used to examine women with intrauterine devices, an exam that can be done in a minute or two, according to Birnholz.

A preliminary study also indicates that ultrasound can be used as a yearly gynecologic examination as a means of locating tumors more reliably than with traditional physical exams.

"One of the benefits of the new equipment is that a thorough study can be concluded quickly, so that large numbers of patients can be seen without delay," says Birnholz. The high-speed phased array system provides "pictures" with good detail, which can be recorded on videotape for permanent reference.

The use of ultrasound in diagnosis is growing throughout the U.S., and has become an established method of examining in pregnancy.

New equipment at Stanford involves the electronic movement of a beam of high frequency sound that is far beyond the range of human perception. At these high frequencies, sound acts much like light rays. Echoes reflected back from objects inside the body are pictured in good detail, including internal organs like the heart, liver, and kidneys.

In recent examinations, Birnholz has recorded the facial profile of a five-month-old fetus, and the pulsing profile of an eight-week-old heart.

Other obstetric uses include early identification of multiple pregancies, a broad spectrum of fetal abnormalities, estimation of fetal maturity, and visualization of the placenta.

Birnholz cites the harmless nature of the ultrasound to both mother and fetus, since the procedure does not involve exposure to ionizing radiation.

The new equipment at Stanford includes instruments produced by Varian Associates and by G.D. Searle & Co.

STANFORD--Jack L. Shepard, chairman and president of Granger Associates, Menlo Park, has been appointed chairman of the Stanford University Medical Center Friends Program.

Dr. Clayton Rich, vice president for medical affairs and dean of the school of medicine, said the Friends Program consists of individuals and organizations in the community and other parts of the country interested in supporting the unique services provided by the medical center.

Shepard will serve on the volunteer post to coordinate and help expand the activities of the group, Rich said.

"A teaching hospital such as Stanford's requires constant modernization of equipment and facilities to keep pace with technological improvements, to apply research findings to patient care, and to train young doctors. These special needs must be supported by gifts.

"Our hospital and clinics operate without endowment or university subsidy, thus differing fiscally from teaching hospitals affiliated with state universities and from community hospitals supported by district taxes."

Shepard, formerly director of development at Stanford University, has been with Granger Associates since 1967.

He is a Stanford graduate of the Class of 1953. He earned a master's degree in education in 1955 and one in business administration in 1957, both at Stanford.

Shepard was nationally known to sports fans as a major league baseball player with the Pittsburgh Pirates during 1954-56.

He has served on other key staff posts at Stanford during major fund drives in the past, and is currently a member of the Stanford Associates, a volunteer group which over the years has provided support to the University's gift program.

STANFORD--Rose Elizabeth Bird, secretary of California's Agriculture and Services Agency, Tuesday, Feb. 3, underwent an operation for breast cancer at Stanford University Hospital.

"She was found to have a type of tumor for which the prognosis for recovery is excellent," said Dr. John Kieraldo, clinical associate professor of surgery.

Miss Bird, 39, checked in at Stanford hospital Monday after her malignancy was discovered during a routine medical examination last week.

She is expected to be out of the hospital by the end of the week, and back to work in Sacramento in two to three weeks, Dr. Kieraldo said.

The state official asked the hospital to issue a statement about her hospitalization because of numerous requests about her condition.

STANFORD--The emergency room of Stanford University Hospital has a new telephone number, 497-5111.

According to emergency room personnel the new number should be easier for people to remember and will also allow better telephone service when the unit moves this summer into the new hospital wing now under construction.

The new number is now in operation. Callers using the old number will hear a recording directing them to dial the new number.

STANFORD--Stanford University Hospital has suspended until further notice its requirement that community physicians on the medical staff carry adequate malpractice insurance.

The action, approved by the Hospital Board of Directors at a meeting Tuesday evening, February 3, is effective immediately.

Physicians who had been suspended by the hospital because they failed to show proof of the required coverage are reinstated. At least 37 physicians, and possibly others who have changed insurance carriers are affected, said Dr. Robert Alway, medical director.

He emphasized that the requirement was eliminated in view of the "current uncertain medical malpractice situation in California and the apparent efforts on the part of the State legislature to solve this problem."

Hospital bylaws had stipulated that physicians on the medical staff show proof of adequate coverage in compliance with a requirement of the hospital's insurance carrier. The minimum individual coverage was $1 million per malpractice case and $1 million aggregate per year for all cases.

Stanford Hospital is a member of the California Hospital Association insurance group administered by Walker and Company of Los Angeles. Last November the member hospitals were notified that unless they certify their staff physicians have adequate malpractice insurance, there would be a 20 percent surcharge added to the institution rate. In Stanford's case, this would have amounted to another $400,000 according to hospital officials.

On January 22, the hospitals were told that the surcharge was discontinued.

STANFORD--Many older persons losing their memory or behaving abnormally are thought to be senile when they are only depressed, according to Dr. Leo E. Hollister, professor of medicine and psychiatry at the Stanford University School of Medicine.

"Unrecognized depression may be a more important problem in old age than organic brain conditions," Hollister reported in an article in the Journal of the American Medical Association.

As many as one in four, or one in three, persons 65 and over have depression or other functional emotional conditions such as anxiety, he said. But only one in six in this age group has some symptom of organic brain condition from hardening of the arteries to other physical damage.

"Because the functional and organic conditions mimic each other, depression in many older persons doubtless is unrecognized," Hollister said.

"Both depression and anxiety usually can be greatly alleviated or cured if properly treated by drugs and psychological means," he added.

Age alone does not necessarily mean that the patient's emotional disorder is due to organic brain disease, Hollister stressed.

"Life has plenty of psychosocial vicissitudes to make the elderly depressed," he said.

Among these are decreased earning power and loss of prestige, illness or death of one's spouse and friends, and isolation.

Also, a stroke or a heart attack is a depressing experience for many of these patients.

"Suicide is common among the elderly," Hollister said, "but many depressions may be missed, either by the patients' families or physicians.

"And since depression is treatable, one should be highly sensitive to its manifestations."

For the one in six individuals whose mental deterioration may be caused by organic changes in the brain, best control of disturbing symptoms is accomplished with tranquilizing drugs.

In the future drugs that alter disturbed brain metabolism may afford a new and possibly more specific approach to treatment, but it is far too early to assess fully their potential, Hollister added.

STANFORD--Dr. Lewis Dexter, internationally known cardiologist, will speak on "Venous Thrombosis and the Chair" at the 12th annual John Kent Lewis Memorial Lecture at Stanford University School of Medicine.

Dr. Dexter, professor of medicine at Harvard Medical School, Peter Bent Brigham Hospital, will speak on Monday, February 9, at 4:15 p.m. in Room M106 of the Medical School. Physicians and other health professionals in the community are invited to attend.

Dr. Dexter played a major role in the introduction and development of cardiac catheterization laboratories in the United States, and has directed that laboratory at Peter Bent Brigham Hospital.

He was part of the team that developed the first mitral valve operation in the 1940s, and is also a widely known clinician and investigator in adult congenital heart disease.

He received his A.B. from Harvard College (1932) and M.D. from Harvard Medical School (1936), and has been associated with Peter Bent Brigham Hospital since 1939. He is also consultant to Children's Hospital Medical Center and Robert Breck Brigham Hospital in Massachusetts.

The John Kent Lewis Lectures are presented annually in honor of the former chief of the Stanford Medical Service at San Francisco General Hospital. A 1922 graduate of Stanford Medical School and noted pioneer in heart research, Lewis died in 1961.

STANFORD--A fund has been established in the Department of Pediatrics at Stanford University School of Medicine to help attract medical researchers into the field of pediatric hematology.

The Scott Dunsford Memorial Fund is named after the four-year-old Aptos, Calif. boy who died at Stanford University Hospital Jan. 10 of aplastic anemia.

The boy had been treated at Stanford for several months for the disease which is characterized by a deficiency of blood cell formation. Those suffering with the disease in its severest form must receive transfusions of blood components, including platelets, which are necessary to prevent internal and external bleeding episodes.

The fund is under the direction of Dr. T. John Gribble, senior attending physician and clinical associate professor of pediatrics. Gribble said the Scott Dunsford Memorial will be utilized as part of the Pediatrics Hematology Fund. This fund supports research into blood disorders, such as aplastic anemia, which primarily effect children.

Dunsford's parents, Charles and Frances Recknagel, said they hope the fund will "attract people that may eventually be able to bring the kind of resources necessary to treat, and possibly cure, this disease (aplastic anemia) and others."

STANFORD--A Stanford University Medical School student has been named the first recipient of an endowed medical scholarship, recently established by the Retail Clerks International Association.

Stanford officials believe that this is the first student aid fund established by an international trade union. The scholarship fund honors the union's current president, James T. Housewright.

Recipient of the first award is John Reeves, first-year medical student. Reeves attended Santa Rosa Junior College, then received his undergraduate degree in sociology at the University of California at Berkeley.

With a California Heart Association grant last summer, Reeves worked on a project dealing with the early prognosis of patients hospitalized with myocardial infarction.

Reeves is married and his wife is working toward an R.N. degree. They have two children.

Recipients of the award may be chosen from medical schools throughout the United States and Canada. The scholarship award is renewable for up to four years for each recipient for a total amount of $5,000.

According to the union, the scholarship originated at a 1973 convention of the Southwestern States Council of Retail Clerks, as a living monument to the union's president and as a way by which the union could help in the training of physicians and surgeons. Other locals asked to be involved and the scholarship was expanded to a permanent fund covering the United States and Canada through gifts from individual union members, other Retail Clerks councils and local unions.

STANFORD--Former baseball great Joe DiMaggio will be among 36 top Northern California golf professionals and ranking amateurs from the corporate world at the Joe DiMaggio Invitational Executive Pro-Am Golf Tournament Friday, April 9, at Half Moon Bay.

Proceeds from the charity event will be donated to the Bay Area Chapter of the March of Dimes and to support dermatology research at Stanford University Medical Center.

Amateur golfers may enter the tournament at the Half Moon Bay Golf Links at Ocean Colony for a $100 entry fee. Those interested should contact Moon Mullins, the resident pro golfer.

Signups will be at 9:30 a.m. at the hospitality desk with a shotgun tee off at 11 a.m. From noon to 1 p.m. lunch will be served on the course for players and working press followed by an informal awards dinner in the evening.

The par-72, 18-hole golf course is located on California's coastline about 28 miles south of San Francisco on U.S. Hwy. 1. The 7,105-yard course opened in 1973 and is ranked among the most difficult in California.

"Joltin' Joe" DiMaggio, who was raised in San Francisco, played 13 years with the New York Yankees, setting a major league record for hitting safely in 56 consecutive games. Inducted into baseball's Hall of Fame in 1955, DiMaggio was voted the American League's Most Valuable Player in 1939, 1941 and 1947. He was also the league's top hitter in 1939, 1940 and 1948, and in 1969 was named baseball's greatest living player by sportswriters and fans.

The public may attend the golf tourney free of charge.

STANFORD--Dr. Julius Axelrod, distinguished pharmacologist with the National Institute of Mental Health and 1970 Nobel Prize winner, will present the third annual Windsor Cutting Lecture at the Stanford School of Medicine on Thursday, April 1, 1976.

Dr. Axelrod will discuss "The Pineal Gland and the β-Adrenergic Receptor" at 4:15 p.m. in Room M106 of the Medical School. The lecture is open to the medical community and the public.

Since 1955, Dr. Axelrod has served as chief of the Section on Pharmacology, Laboratory of Clinical Science, of the National Institute of Mental Health, Alcohol, and Drug Abuse Administration.

His fields of interest include the biochemical mechanisms of drug and hormone actions, drug metabolism, enzymology and study of the pineal gland.

His work on the metabolism and synthesis of neurotransmitters, compounds involved in chemical transmission in the nervous system, brought him the Nobel Prize for physiology or medicine in 1970.

Dr. Axelrod began his career as a laboratory assistant in the department of bacteriology at New York University Medical School in 1933. He served as chemist with the Laboratory of Industrial Hygiene for several years, and in the research division of New York University at Goldwater Memorial Hospital. He joined a celebrated group of investigators at the National Heart Institute in 1949 before joining the Institute of Mental Health in 1955.

He serves on the editorial boards of many publications, has received numerous awards for distinguished service, and is the author of more than 400 scientific publications.

The Windsor Cutting Lectureship was established in 1973 by the faculty of the Department of Pharmacology and is supported by private contributions. It honors the memory of Dr. Cutting, professor and former chairman of the department, who also served as dean of the School of Medicine, 1953 to 1957, and dean of the University of Hawaii Medical School, 1963 to 1971. Dr. Cutting died in 1972.

The lectures feature speakers prominent in the field of pharmacology, and are given annually during the winter quarter.

STANFORD--Dr. Ronald W. Davis, assistant professor of biochemistry at Stanford University Medical School, has been named 1976 recipient of the Eli Lily and Co. Award in Microbiology and Immunology.

The award is presented annually to an outstanding scientist under 35 years of age and includes a medallion and $1,000. Davis will accept his award at the 76th Annual Meeting of the American Society for Microbiology in Atlantic City, N.J. He will deliver the award address on May 3.

In graduate work at the California Institute of Technology (CIT), Davis developed the electron microscope heteroduplex method of investigating the sequence of nucleic acids, an analysis which has had significant uses in mapping sequences in DNA molecules.

A well-recognized electron microscopist, Davis received a postdoctoral fellowship to Harvard, where he was involved in DNA and virus molecular biology.

Davis, 34, came to Stanford in 1972 as an assistant professor of biochemistry, where his research emphasis has been on gene manipulation. His laboratory has developed techniques for joining fragments of cleaved DNA together for viable recombinant DNA. More recently he has worked on a derivative of a bacteria virus that can only multiply if it incorporates foreign DNA segments, a technique that may have important applications in the future.

Davis earned a B.S. degree in 1964 from Eastern Illinois University and undertook graduate studies at CIT, where he had an NIH predoctoral traineeship from 1964 to 1970.

STANFORD--Gifts totaling $11,920 have been presented to Stanford University Medical School for neurological studies and for educating medical students engaged in cancer research.

The gifts were made available by the California Community Foundation of Los Angeles, a publicly-supported trust which distributes funds for charitable purposes.

The foundation earmarked $5,012 from its Jane Reinking-Killgore Fund to be used in Stanford's Department of Neurology for studies into the effects of injury, occurring in early life, on the function of brain nerve cells.

These studies, which are being directed by Drs. David A. Prince and Philip A. Schwartzkroin, were begun under a similar foundation grant last year. Ultimately, both researchers hope it will be possible to specify the basic nerve cell abnormalities which result, and devise treatments that will prevent or correct them.

A total of $6,907 from the foundation's Esther Sparks Cross Fund will be used for scholarships to support "the education of promising and needy medical students engaged in cancer research."

Last year the California Community Foundation gave $1.3 million to 212 charitable and educational institutions. It is one of the largest community foundations in North America.

STANFORD--Two key administrative appointments have been announced at Stanford University Medical Center.

Ronald D. Twomey has been appointed medical center director of personnel while Margaret Neill has been named associate director of Stanford Hospital and director of Nursing Service.

Neill begins her new duties April 1 while Twomey expects to be on the job in early May.

According to Peter Carpenter, assistant vice president for medical affairs, Twomey will head a newly formed office consolidating the other major personnel activities of the medical center. In addition to hospital personnel, Twomey's office will also serve Stanford School of Medicine, Hospital and Clinics within the framework of general university policies, procedures and contractual commitments.

Twomey is currently the director of personnel relations and organization (the National Health Care Industry Program) for Arthur Young and Co., Chicago, a consulting firm.

From 1967 to 1974 he was associated with the University of Chicago Hospitals and Clinics, serving as associate administrator, assistant administrator and personnel director.

Twomey was also director of personnel at Dee Memorial Hospital in Ogden, Utah, a contract administrator and negotiator for the Thiokol Chemical Corp. of Ogden, and a psychologist for the Utah juvenile court system, 1958-60.

A native of San Francisco, Twomey earned a bachelor of science degree in industrial psychology from the University of Utah in Salt Lake City. He has also undertaken graduate work at Utah, as well as at the University of Chicago and at Loyola University in Chicago.

For the past 10 years Neill has been director of nursing and assistant administrator at University Hospital, University of California Medical Center, San Diego.

She succeeds G. Darlene Lutts, who resigned in January, 1975. In the interim, Lois Williams has served as acting director of the hospital's Department of Nursing Service.

Prior to joining U.C. San Diego, Neill served four years as associate director of nursing at Valley Medical Center in Fresno. She holds a bachelor of science in nursing from the University of New Mexico in Albuquerque and a master of science in nursing from UCLA. ###

STANFORD –

Plans to begin activating Stanford University Hospital's new $12.6 million wing next month may be delayed, Paul Hofmann, director of the hospital and clinics, said today.

The building had a preliminary inspection April 23, Hofmann said. The inspectors found some potential code deficiencies and will notify the architect and contractors so that they can be corrected.

Robert Bowen of the State Bureau of Licensure and Certification declined to list the problems until he issues a report. "But they are not insurmountable," he said. "The building is a good structure. When you deal with a physical plant of this magnitude, there are bound to be clean-up type problems."

Bowen said the "preliminary visit" was conducted for the purpose of reviewing the project at this stage to advise the architect and contractor.

Others on the inspecting team were fire marshals from the state, Palo Alto, and Santa Clara County, and two federal officials representing programs for the handicapped and the Hill-Burton Hospital Construction Act.

James E. Nelson, director of facilities and properties at Stanford, said that some parts of the building may have to be modified if they fail to meet hospital building code requirements.

But Stanford has not yet received a written report from the inspectors. Information on any required modifications is expected in a few days, he said.

Hofmann explained the hospital had expected to receive the completed wing in May, and to admit its first patients in July.

The project, designed by Caudill Rowlett Scott (CRS) of Houston and Los Angeles, will add 25 intensive care beds and increase emergency services facilities. Expansion also includes vitally needed services in X-ray, surgical pathology and cardiology and postanesthesia recovery.

STANFORD--Learning and educational problems of the sleepy child will be studied by researchers at Stanford University School of Medicine beginning this summer.

The study, directed by Dr. William C. Dement, professor of psychiatry and behavioral sciences, will be funded by a one-year $40,550 grant from the Spencer Foundation of Chicago.

"Excessive daytime sleepiness," said Dr. Dement, "is believed to have a damaging effect on learning and school performance."

He indicated that some children have been diagnosed as mentally retarded while their sleepiness was overlooked.

"All but the rudimentary learning and memory functions are inoperative during sleep," Dement explained. "However, the effects of sleepiness must be understood in the child, and a clear relationship between sleepiness and the degree of impairment must be established."

In his study Dement will be assisted by Drs. Thomas C. Anders, Vincent P. Zarcone, Christian Guilleminault, and consultants from the School of Education, and the Department of Psychology.

Plans will be worked out with parents and school authorities to administer questionnaires to high school, junior high, and elementary school students.

Children identified as "sleepy" will be tested in the Stanford Sleep Research Laboratory for learning, memory, and presence of organic disease, and then matched in terms of age, sex and I.Q. with a normal control group.

Others in the study will include children referred to the Stanford clinics for sleep problems and learning difficulties.

Dement said these specific areas will be studied:

--To what extent is intellectual performance a function of sleepiness? Can school performance be correlated with overall sleepiness ratings?

--What are the individual variations in amount of daytime sleepiness in school children? Can they be changed?

--To what extent is severe or borderline pathological sleepiness overlooked in school children?

"Pilot work in our laboratory," Dement explained, "suggests that children who undergo a fairly small reduction of habitual sleep during the night feel sleepy the next day."

STANFORD--What initially began as a suggestion during a ride to a San Francisco cocktail party has blossomed into a full-sized recipe book, catchingly entitled The Happy Cooker., compiled and edited by a small group of Stanford University Hospital nurses.

The book, which embodies "favorite recipes of the nurses," is primarily the brainchild of two nurses, Marie Murphy and Pat Pocek, who were joined by Belle Pullano, Dorcas Walton and Mary Sheehan in the project. Another nurse, Joanne Hendricks, designed the book's cover that features a Pennsylvania Dutch motif.

"We began collecting recipes last spring," Murphy explained, "and we put the word out to people on the floor, including dietitians and housekeepers, they could contribute if they wanted to. We even had the wife of one of our patient's bring in a birthday cake, the recipe for which is in the book."

After six weeks of recipe collection, the nurses arranged for typesetting and layout work to begin. They were aided and advised by Gregg Pullano (Belle's husband), who works for a publishing company.

"We must have spent a thousand hours apiece on this project," Murphy noted, "at least it seemed that way."

Murphy said she was able to help considerably since she was confined to restricted work on the floor for nine months following right knee surgery. "The book was great for me then because I needed some kind of mental activity to keep my sanity."

Ironically, Murphy noted, The Happy Cooker. is loaded with recipes for high caloric and high cholesterol foods (including 11 cream cheese recipes) even though her hospital wing (East 2A) treats many cardiac patients.

As a result, several proposed book titles were eventually rejected by the nurses, including "Heart Disease With Ease," "Eat Your Way to East 2A," and "Prescriptions for the Pantry." The 160-page book was printed by David Moody of Mountain View.

-more-

222--The Happy Cookers

Aside from the other pastries and desserts ("one-third of our book"), Murphy pointed out that the many cheesecake recipes range from the "never fail" variety to one that takes three days to prepare.

The book also gives recipes for appetizers, salads, noodles, breads and miscellaneous items. Furthermore, it offers dishes of unusual faire such as cream cheese enchiladas, pork chops with grape jelly and pork roast with peanut butter.

STANFORD--A bequest of more than $1.7 million for medical research has been received by the Stanford University School of Medicine from the estate of John S. Ladd of Stockton.

Ladd died in February 1974, naming the Medical School as his beneficiary.

"The School is honored to receive this bequest and to establish the John S. Ladd Medical Research Fund in his memory," said Dr. Clayton Rich, vice president for medical affairs and dean of the School. "This fund will support medical research of the highest quality, and we are most grateful for it."

John (Jack) Ladd was the only child of John S. Ladd, Sr. and Mary Ladd, whose families settled in California in the early 1880's. The senior John S. Ladd was postmaster general in the Philippines at the turn of the century. Later, he returned to farm in the Stockton area.

Mr. Ladd graduated from Stockton High School and the University of California at Davis, where he received a degree in agriculture. He served in the South Pacific during World War II as a captain in the artillery. After the war, he returned to Stockton where he was engaged in various farming operations until his death at age 53.

STANFORD--A fellowship grant from the Damon Runyon-Walter Winchell Cancer Fund has been awarded to a postdoctoral research fellow at Stanford University Medical School.

The $14,800 grant to Dr. Shlomo Eisenberg in the Department of Biochemistry will support research on the control of DNA replication, under the direction of Dr. Arthur Kornberg, Stanford professor of biochemistry.

Dr. Eisenberg's research concerns the molecular mechanisms involved in the process and control of DNA replication. That research, according to Dr. Kornberg, should be of significant value in the pursuit of an understanding of the cancer process.

Dr. Eisenberg completed undergraduate work at Hebrew University in Jerusalem, and received his doctorate in biochemistry at McGill University, Montreal.

The Runyon-Winchell Fund is a charitable organization that provides support for cancer research in the form of fellowship grants. The grants assist in the training of young investigators pursuing careers in cancer research.

STANFORD--Dr. Rosalyn S. Yalow, a pioneer in the development of radioimmunoassay techniques, will present the third annual Katharine D. McCormick Distinguished Lecture April 8 at 4 p.m. in Room M106 at Stanford University School of Medicine.

Yalow, whose address is entitled "Radioimmunoassay: Its Role in Clinical Medicine," is a distinguished service professor at Mt. Sinai School of Medicine, New York City, and chief of Nuclear Medicine Service at Veterans Administration Hospital in the Bronx.

She is well known for the development of the first radioimmunoassay, for circulating insulin, and for similar methods she developed later for gastrin, ACTH, somatomedin and other hormones. These techniques have opened new areas of investigation and understanding of the function of polypeptide hormones in normal human physiology and in disease states.

Originally trained as a physicist, Yalow received her Ph.D. in physics at the University of Illinois in 1945, and worked as a physicist at the Bronx V.A. Hospital until 1970, during which time she developed the initial radioimmunoassay techniques. She has been a member of the President's Study Group on Careers for Women since 1966.

The McCormick Lecture was established to bring outstanding women scientists and physicians to Stanford Medical School. It honors the late Katharine Dexter McCormick, who left a $5 million bequest to Stanford in 1969 to aid programs in the medical school, particularly those "for the encouragement and assistance of women in...medicine." The lectureship was initiated in 1974 at the suggestion of the Professional Women of Stanford Medical School.

FOR IMMEDIATE RELEASE
STANFORD –

Consumerism has touched many areas of life from food to transportation and even the cost of burial. Now a Stanford physician has coauthored a consumer's guide to medical care.

Dr. James F. Fries, an assistant professor of internal medicine, and Dr. Donald M. Vickery, director of the Reston, Virginia, Medical Center tell how to become an englightened consumer in *Take Care of Yourself,* a consumer's guide to medical care (Addison-Wesley Publishing Co., Reading, Massachusetts 1976, 269 pgs., $5.95 paperback, $9.95 hardcover).

The book provides decision charts and home treatment information for 68 of the most common medical problems ranging from dandruff and chest pain to flu and burns.

For each problem, the doctors provide a brief description of the condition, suggest home treatment, and indicate symptoms which warrant a physician's attention and whether that attention should be immediate. The reader is told what to expect at the doctor's office, from the type of history the doctor may require for that particular ailment to diagnostic tests and finally, possible treatments that may be prescribed.

The handbook helps the consumer find a physician and suggests the need for an annual checkup is a myth. Most tests that should be done annually, the authors state, often can be provided at little or no cost by the public health department.

The authors recommend regular checks of blood pressure, skin tests for tuberculosis every few years, regular Pap smears for women over 25 and breast self-examination each month, a periodic glaucoma test, urinalysis, urine cultures, and tests for blood in the stool after age 30 for high-risk individuals.

The doctors remind us "The best health maintenance strategy is to seek medical care promptly whenever a truly important complaint or finding occurs. If you find a lump in your breast, if you have unexplained weight loss, if you have begun to cough up blood or run a fever for more than a week, then you should seek medical attention without undue delay.

They suggests further ways to reduce health care costs by teaching consumers to have their doctors prescribe generic drugs. Pharmacies carry variously priced generic drugs, and the authors recommend that you shop around to find the best value.

Home remedies for problems such as skin dryness, fever, warts, and upset stomachs are suggested which the doctors feel can save even more money for the consumer, in addition to providing him with the knowledge to choose the product which will be most effective.

A section "For Women Only" describes how to do a breast self-examination and what to expect at a gynecological examination. It also deals with menstruation and venereal disease.

A useful "Family Records" section is provided at the end of the book for the consumer to keep track of immunizations, childhood diseases, blood types, RH factors, allergies, and hospitalizations. Space is provided for important telephone numbers.

In addition to saving money for the consumer, Fries and Vickery hope to alleviate the growing demand for physician services by providing guidelines on when to seek medical attention. Perhaps more important, according to the authors, "by learning to identify the significance of medical problems, the consumer can ensure that professional medical care is obtained when it is needed. With this information you can take good care of yourself and your family."

STANFORD--Dr. Victor Richards, a long-time San Francisco surgeon, is new president of the Stanford University Medical Alumni Association. New officers were named at the May 21 meeting of the Board of Governors of the association.

Dr. David A. Rytand, Bloomfield Professor of Medicine emeritus at Stanford and chief of cardiology at Santa Clara Valley Medical Center in San Jose, was named president-elect.

Dr. Richards, a member of the class of 1939, will serve as president through June 1977, succeeding Dr. Paul Campbell of Portland, Oregon.

Dr. Richards joined the Stanford faculty in 1943 and served as professor and executive head of the Department of Surgery from 1955 to 1958 before the School moved to the Stanford campus.

He has continued his association with the Medical School as a clinical professor of surgery, and has been long active in the Alumni Association. He is currently chief of surgery at Children's Hospital of San Francisco.

A member of the class of 1939, Dr. Rytand has served several terms as secretary-treasurer of the Alumni Association. A specialist in renal and cardiovascular medicine, he has been a member of the Stanford faculty for more than 35 years. From 1954 to 1960 he was executive head of the Department of Medicine.

Dr. Don Goffinet, class of 1964, and assistant professor of radiology at Stanford, has been elected new secretary-treasurer of the medical alumni group.

New members of the Board of Governors are Dr. Anthony Engelbrecht, class of 1962, of Lafayette, and Dr. Frank Norman, class of 1944, Santa Rosa. Reelected to three year terms are Drs. Norman M. Christensen '48, James A. Clever '62, and S. Gainer Pillsbury '57. ###

STANFORD--An unrestricted gift of $6,826 has been given to Stanford University Medical School by the American Medical Association-Education and Research Foundation (AMA-ERF).

The check was presented to Dr. Clayton Rich, vice president for medical affairs and dean of the school of medicine, at a recent meeting of the Santa Clara County Medical Society.

The gift is part of the AMA-ERF contributions given annually to medical schools to support training of physicians. The funds originate from donations by individual physicians, AMA Auxiliary members and others across the country.

Funds from the gift will be used to support instructional materials at Stanford's Fleischmann Learning Center through the use of the Health Education Network. ###

STANFORD –

A brain-wave pattern assumed until recently to be associated with epilepsy is being studied to determine if in fact it occurs in normal people.

Normal persons between the ages of 10 and 65 are needed to aid in the countywide research program, according to Dr. Timothy A. Pedley, acting director of the EEG (electroencephalograph or brain-wave scan) Laboratory at Stanford University Medical Center.

Dr. Pedley, Dr. James White of the San Jose Medical Clinic, and Dr. J. William Langston, chief of neurology at Santa Clara Valley Medical Center, are the principal investigators. Dr. Pedley says that 200 "entirely normal individuals" are needed for the study.

The doctors will be looking for a spike-wave pattern which for many years has been associated with psychomotor epilepsy. Along with many other factors this pattern has been used in the diagnosis of epilepsy.

Recently, however, the significance of this particular spike-wave pattern has been questioned, with some doctors suggesting that the pattern may not be abnormal at all, occurring as frequently in normal individuals as in epileptics.

"If this is true," says Dr. Pedley, "then it is possible that some patients have been incorrectly diagnosed as having abnormal EEG patterns."

Until this definitive study is completed, perhaps in six months, this particular brain wave is being interpreted with caution, says the neurologist. While a diagnosis of epilepsy is not made on the basis of the EEG alone, it has been decisive in borderline cases.

Dr. Pedley has no estimate of the number of persons whose epilepsy was diagnosed on the basis of the EEG; he feels it is a "small number of persons but it is a diagnosis of great importance to them.

"The individual thus labeled immediately becomes subject to all the restrictions and handicaps imposed by society on epileptics. It may mean almost certain loss of driving privileges, limitation of certain physical and recreational activities, and in some persons, such as truck drivers, ariline pilots and high-rise construction workers, it may threaten their jobs."

About 50 normal volunteers have been examined already in the study. Doctors have little difficulty in locating persons under age 35 who wish to volunteer, but the hardest group to find have been those from age 40 to 65.

He stresses that there is no risk or pain in having an EEG. "There may be a slight inconvenience for some volunteers since they are asked to stay awake the night preceding the test. This is because the EEG pattern we are interested in occurs mainly in the light stages of sleep and may even be activated by sleep deprivation."

Volunteers may call the EEG Laboratory of any of the three medical centers participating in the study. They will be sent a questionnaire and consent form to insure that nothing in their past medical history disqualifies them from participating. An appointment may be made on a weekend if necessary.

Interested persons may call the Stanford EEG Laboratory at 497-7181; the San Jose Medical Clinic, (408) 998-5551 extension 380; or the Santa Clara Valley Medical Center EEG Laboratory at (408) 293-0262 ext. 520.

The study is being sponsored by grants to the Stanford Department of Neurology, by the San Jose Medical Clinic Research Foundation, and by the Santa Clara County Epilepsy Society.

STANFORD –

Stanford University Hospital's new wing is expected to be completed by Sept. 1 and may be ready for patients in December, according to Hospital and University planning officials.

Original plans called for activation of the new wing in July. Those plans were delayed after a preliminary inspection in April revealed a variety of code and licensing deficiencies.

Cassius Kirk Jr., University staff counsel, said that a claim against the architectural firm of Caudill Rowlett Scott of Houston and Los Angeles has been filed for an undisclosed, but substantial amount.

Philip Williams, director of planning, said that construction of the $12.6 million wing and correction of building code deficiencies is expected to be completed within the budget planned. Additional costs because of delays and design changes have not been established, he said.

The project will add 25 intensive care beds and increase facilities for emergency services. The expansion also includes services in X ray, surgical pathology, cardiology, and postanesthesia recovery.

According to James McNally, director of facilities at the Medical Center, work is now underway to make necessary corrections and additions indicated by the preliminary inspection.

Problems are in three categories: hospital building code requirements, state and federal licensing requirements for patient care, and functional modifications requested by the departments.

The inspecting agencies include the State Bureau of Licensure and Certification, the State Facilities and Construction Section, federal officials representing programs for the handicapped and the Hill-Burton Hospital Construction Act, and fire marshals from the state, Santa Clara County, and Palo Alto.

Inspectors called for changes, for example, in doors, restrooms, plumbing fixtures, and wall and ceiling surfaces. Departments to be located in the new wing have described such problems as proximity of ambulance access, placement of reception areas, and adequate preparation of rooms for installation of equipment.

These problems are now being addressed by the Hospital engineering group and the architects, according to McNally.

STANFORD--Mrs. Rebecca Ahl Northway, 69, wife of the late Dr. William H. Northway, a distinguished Stanford physician, died Friday, May 21, 1976, of cancer at her home at Channing House in Palo Alto.

Mrs. Northway had been closely associated with Stanford University Hospital and the Medical School since 1927, when she entered the Stanford School of Nursing. From 1964 until her retirement early this year, she was familiar to many as receptionist at the Information desk at Stanford Hospital.

Born October 18, 1907 in Mowequa, Illinois, she came to Modesto, California with her family in 1925. She graduated from Modesto Junior College in 1927 and entered Stanford Nursing School.

Upon Graduation in 1930 she was married to Dr. Northway, who that year received his M.D. from Stanford. The two came to Palo Alto in 1932, and Mrs. Northway served as a nurse at the Stanford student health service.

Dr. Northway through the years served as chief of clinics, assistant dean of the Medical School, and acting physician-superintendent of Stanford Hospital. He also served on the governing board of Palo Alto-Stanford Hospital. Dr. Northway died in 1960.

Three sons survive, all Stanford graduates. William H. Northway, Jr., A.B. '54 and M.D. '57, serves as associate professor of radiology and pediatrics, director of the diagnostic division and associate chairman of the department of radiology at Stanford. Dr. J.D. Northway, A.B. '57 and M.D. '60, practices in Indianapolis, Ind. John C. Northway, A.B. '62 and M. Arch. '67, is a Palo Alto architect.

Mrs. Northway was an active member of the Stanford Faculty Wives Club, the Stanford Hospital Auxiliary, and the Allied Arts Guild to the Palo Alto Auxiliary of the Children's Hospital at Stanford.

Memorial services will be held by Roller & Hapgood Mortuary, Palo Alto, with private internment in Alta Mesa Cemetery.

The family prefers that gifts be directed to the William H. Northway Memorial Book Fund, in care of the Office of the Dean, Stanford University School of Medicine.

STANFORD--Establishing balanced public policies to deal with potential hazards from chemicals and radiation is impeded by public ignorance of the dangers and by consumer activists with insufficient scientific data, according to Dr. Joshua Lederberg, Nobel laureate geneticist at Stanford.

It is possible that man is subjecting himself to significant risks from a wide array of chemical substances and radiation, said the geneticist, but there is not enough scientific work being done to adequately weigh the dangers against the benefits.

Lederberg discussed the implications of altering genetic factors during a clinical symposium at the Stanford School of Medicine's alumni reunion day on Saturday, May 22.

He noted that ionizing radiation is the most widely discussed method of potentially increasing mutations--genetic changes--and carcinogenetic, or cancerous changes in man.

Average levels of radiation from natural causes in the atmosphere are from 100 to 200 millirads, he said, and 30 to 50 millirods from diagnostic X rays in medicine. Radiation from nuclear power plant leakage or fallout from nuclear testing, he says, amount to very small fractions.

Medical usage, he said, is the single largest source of artificial radiation exposure, and one that he feels could be reduced.

Chemical compounds also may cause changes in the genetic material of human cells.

"There are reasons to believe that the chemical environment may be even more serious in causing mutations than the radiation environment," says Lederberg. He calls for "judicious biological, chemical, and economic analyses of environmental health." Proper testing, he says, should occupy a much higher priority than it does now.

Such testing, he said, must involve animal studies, and "it is entirely appropriate to extrapolate from animal studies to what the general population will experience when it has correspondingly lower doses."

-more-

Testing of cyclamates had been criticized, he said, for not being relevant to humans. Extremely high doses had to be given the animals before any adverse effects were seen.

This led to some complacency by the public, said Lederberg, which was not warranted, and obstructed the need for doing necessary scientific work.

Testing food additives such as cyclamates in humans at high enough levels to achieve adverse results would be unacceptable, he said: "there would not be many people left after a few years to comment on the situation."

Regarding the use of nitrite in food additives, Lederberg said that at first it looked like a horror story, with large quantities of the material being used in a wide range of foods, such as bacon, ham and frankfurters. But he also noted the economic value of the compound as a disinfectant and preservative, and said that more scientific studies are needed to find out precisely what happens to the compound when foods treated with it are ingested by man.

The geneticist also expressed concern about the lack of proper investigations into the use of chlorine. He noted the obvious importance of the chemical for disinfection, but he also called attention to the high chemical activity of the agent, which can react with DNA, the genetic material in human cells, and result in mutations. "We don't know if chlorine could be a hazard to human health, or if there are differences between tests and what happens when it is swallowed by humans in water, but we ought to find out more about this.

"Maybe we shouldn't rely on chlorination so much, although alternatives may be expensive; we don't know if the detriment outweighs the advantages."

In other chemicals already proven toxic at high doses, such as vinyl chloride, he asks if the vigilence is adequate in relation to the mutagenic potential. "Just how bad would one millionth of a lethal dose be when the entire population is exposed," he asks.

Regarding the exposure of people to diagnostic X rays, Lederberg noted that a halving in the levels of medical radiation could result in a two percent decrease in the human mutation rate.

He noted that about five percent of human health problems are of mutation origin. "That would amount to about one tenth of one percent decrease in the health burden by reducing the use of diagnostic X rays. On the average, such X rays are undoubtedly far more beneficial than harmful, but the opposite may be true in a significant proportion of X rays that are taken for defensive motives, rather than in the prudent interest of the patient." ###

ADVANCE--FOR PM PAPERS SATURDAY, MAY 22, 1976, to coincide with Dr. Lederberg's address at 11 a.m. at the Stanford Medical Alumni Reunion Day.

STANFORD--Researchers at Stanford University Medical School have received a grant of $120,000 from the National Institutes of Health (NIH) to continue their studies into narcolepsy, a chronic sleep disorder that affects an estimated 200,000 Americans.

The two-year grant will enable the Stanford researchers to study dogs afflicted with the disease.

According to Merrill Mitler, associate director of the Stanford Sleep Disorders Clinic and Laboratory, the studies are centered on the genetic influences, neurophysiological defects and pharmacological treatments of narcolepsy. Principal investigator of the study is Dr. William Dement, director of the Sleep Disorders Clinic.

Narcolepsy is fundamentally a disease of REM sleep, a state of sleep found in mammals, including man. The main features are rapid eye movements (REM), and paralysis of voluntary muscle. Most persons dream during the several episodes of REM sleep that occur each night.

In narcolepsy something goes wrong with the REM mechanism, Mitler noted. "There is an abnormality of the central nervous system that somehow leads to a disorganization of sleep and components of sleep."

The first signs of narcolepsy usually begin to trouble the narcoleptic patient during puberty.

Mitler says there is no known cure for the disease which is diagnosed in humans by four symptoms: an irresistible urge to sleep, muscular weakness often leading to a complete collapse during excitement, frightening hallucinations prior to the onset of sleep and immediately after awakening, and paralysis during these latter periods.

"Narcoleptic dogs represent one of the major hopes for an eventual cure," Mitler said, "because we can study the sleep mechanism in dogs that have developed the disorder naturally."

-more-

Mitler noted that narcoleptic dogs have symptoms similar to humans possessing the malady. The most noticeable, he said, is a general "collapse" when they become excited, such as when eating or playing. The disease seems to occur mostly in poodles, Doberman pinschers and dachshunds.

One of the continual problems with the studies, Mitler explained, is obtaining additional dogs.

"New additions to our dog colony are well cared for," he noted. "In fact, they are much safer here than if they were running free. Our interest is in precisely observing their usual sleeping behavior and in improving their conditions."

Mitler said narcolepsy is often confused with epilepsy in some dogs while other affected dogs might go unnoticed altogether. "The result is that many of the dogs are destroyed because their owners no longer find them acceptable pets."

One of the major areas the Stanford researchers wish to study is hereditary of narcolepsy in dogs.

Mitler explained that several breedings in the sleep lab of an affected poodle named Monique failed to produce one narcoleptic among her four pups. At the same time, he said, there are two female Doberman pinschers from the same liter with the disease.

"It raises a major question as to whether canine narcolepsy is hereditary. We just haven't had enough dogs yet to study."

STANFORD--Two Stanford medical school faculty members have been appointed to the nine-member regional Medical Quality Review Committee serving Santa Clara County, Gov. Brown's office announced Tuesday (May 18).

The Stanford appointees are Dr. Robert H. Alway, professor of pediatrics and medical director of Stanford University Hospital; and Frances K. Conley, assistant professor of neurosurgery.

Also named were three community physicians who also teach at Stanford. They are Dr. Joseph H. Davis, clinical associate professor of pediatrics and chief of pediatrics at the Palo Alto Medical Clinic; Dr. Philip M. Lippe, clinical associate professor of surgery, San Jose; and W. Warren Mills, clinical assistant professor of medicine, Los Altos.

The committee is one of 14 regional subgroups of the Board of Medical Quality Assurance (formerly the State Board of Medical Examiners). The purpose of the committees is to review medical quality care practices, to investigate public complaints, and investigate the standards of practice of physicians involved in malpractice suits.

EDITORS: Review copies of the book are available upon request.

STANFORD--A Stanford cardiologist concerned with preventing heart disease, and a Palo Alto cooking teacher concerned with preparing fine food, have put together a new cookbook of exotic and simple cuisine--all low in saturated fats, cholesterol, and calories.

A guide to the levels of fat, cholesterol, and calories is included for each recipe in the Whole Family Low Cholesterol Cookbook by Helen Cassidy Page and Dr. John S. Schroeder, (Grosset and Dunlap, New York 1976, 334 pps., $10; paperback $5.95).

The cookbook is not a weight-reduction diet book, not is it for the cardiac patient on a stringent diet, say the authors.

It's aim is to reflect current medical opinion about restricting dietary cholesterol and saturated fat for people of all ages in hopes of preventing heart disease, according to Dr. Schroeder, assistant professor of medicine (cardiology) and director of the coronary care unit of Stanford University Hospital.

"There is now considerable scientific medical evidence that dietary modifications can reduce abnormally high serum fats and hopefully the development or progression of cholesterol deposition in the heart's coronary arteries.

"Several studies have now definitely shown that even minor changes in daily intake of cholesterol and saturated fat will lower blood cholesterol in the average person. The time has come for all of us to modify our diet," says Schroeder in the introductory chapters.

For the cookbook, Mrs. Page contributed a range of recipes from canapes, sauces, fish and meat, to breads and desserts. She assures her readers "all the recipes have been tested and passed with flying colors." Suggested menus include lamb curry, duck, flaming veal smetana, rack of lamb; hollandaise, mayonnaise, and even chocolate sauces, spiced cake and cherries jubilee.

-more-

She also prepared chapters on kitchen tips and equipment needs, cooking techniques, and a chapter on "Cooking as an Art."

According to Dr. Schroeder, medical evidence suggests limiting the daily intake of cholesterol to 250 to 350 milligrams and saturated fat to 30 to 35 grams.

The book's "Three Spoons" signpost next to each recipe indicates up to four "C"s for increasing cholesterol levels, and up to four "F"s for saturated fat levels. A third "spoon" indicates the calorie content of one serving of the recipe. The authors suggest that no more than four "C"s or four "F"s be eaten at any one meal.

The authors point out that the body cannot use or excrete more than about 500 mg of cholesterol per day, the equivalent of two eggs. More than that amount may increase blood levels over a period of time, leading to deposits of cholesterol in the walls of coronary arteries which can gradually slow the blood flow to the heart.

Eating saturated fats--usually these are animal fats that are solid at room temperature, found primarily in animal meats and dairy products--causes cholesterol rises.

"Substituting vegetable oils--polyunsaturates--almost always results in a lowering of these fats in the blood stream, because the body does not make cholesterol from them," says Schroeder.

The authors urge that unless a person has a serious heart condition it is not necessary to abruptly change family meals. They recommend gradually replacing potentially harmful items with healthful ones, without drastically affecting lifelong food likes and dislikes. A unique feature of the book is a suggested six-month program to achieve that.

"We suggest moderate changes in food intake...eating more fresh fruits and vegatables, smaller portions of meats, cereals, starches, sugars and fats, using fewer sauces and fried foods, serving fewer desserts, will do more to help weight control than endless counting of calories," says the cardiologist.

Under Dr. Schroeder's direction in 1973 the Hospital began serving patients a model, low-fat menu as part of an educational program on the role of diet in heart disease prevention. A graduate of the University of Michigan Medical School, he is noted for his studies of contributing factors in heart attacks and evaluation of high risk cardiac patients.

Mrs. Page offers cooking lessons at the "Helen Page School of Cooking" in Palo Alto, and is also a secretary to Dr. Michael Eliastam, director of the Hospital emergency services.

Nutrition consultant for the book was Phyllis Ullman, chief dietition with the Stanford Heart Disease Prevention Program.

FOR IMMEDIATE RELEASE

STANFORD –

"The ABC of Hepatitis Virus" will be discussed in the fourth annual Edwin W. Schultz Memorial Lecture on Thursday, May 20, at Stanford University School of Medicine.

A noted virologist, Dr. Joseph Melnick, professor and chairman of the Department of Virology and Epidemiology at Baylor College of Medicine, Houston, Texas, will be the speaker in room M-106 of the Medical School at 4:15 p.m.

Dr. Melnick is dean of graduate sciences at Baylor, and in 1964 received the school's distinguished service professorship award.

He has contributed to understanding of the nature of defective viruses and the mechanisms of viral carcinogenesis. He also pioneered in the development and testing of dye-light therapy, photodynamic therapy for patients with herpesvirus infections.

Prior to joining the Baylor faculty, he served as head of the virology laboratories of the Division of Biologic Standards of the National Institutes of Health.

The Schultz lectureship honors Dr. Edwin W. Schultz, who served as chairman of medical microbiology at Stanford for 33 years. At his death in 1971 his family and friends established the memorial lectureship.

STANFORD--Alumni of the Stanford University School of Medicine will gather for their Spring reunion day on Friday, May 22, at the Medical School.

In a morning symposium, Dr. Henry S. Kaplan, holder of the Maureen Lyles D'Ambrogio Professorship in Radiology, and director of the Louis B. Mayer Cancer Biology Laboratory, will speak on "Carcinogenesis."

Dr. Joshua Lederberg, chairman of the Department of Genetics and endowed Joseph D. Grant professor of genetics at the School, will also speak during the morning clinical symposium. His subject will be "Mutagens, Carcinogens and Public Health Policy."

Following luncheon for alumni, associates, spouses and faculty in the Grant Courtyard of the School, Dr. Sherman Mellinkoff, dean of the UCLA School of Medicine and a Stanford alumnus, will present the keynote address. His subject will be "The Federal Government and Medical Education."

An additional afternoon address will be made by Dr. Elliott Levinthal, director of Stanford's Biomedical Instrumentation Laboratory. He will discuss "Stanford's Trip to Mars," at 3 p.m. in room M106 of the Medical School.

STANFORD--A new program of professional education, clinical care and research in various aspects of aging will be launched by the Stanford University School of Medicine and the Palo Alto Veterans Administration Hospital.

The new program will be headed by Dr. Leo Hollister, professor of medicine and psychiatry.

Hollister, 55, an internationally known researcher in clinical pharmacology, will direct the effort at the newly developed Geriatric Research, Education and Clinical Center (GRECC) based at the VA Hospital.

The center is one of seven designated by the Veterans Administration to deal exclusively with care of the aged. Two of the centers are in the Los Angeles area, one is in Seattle.

Hollister said the program stems from concern that one-fourth of all patients in VA hospitals are age 65 or older. The number will increase as the largest group of veterans from World War II approach that age.

"Older patients often manifest chronic diseases," Hollister explained. "The process of aging is also accompanied by major physiologic, immunologic, and endocrine changes. Our knowledge in these areas of aging is limited."

Scientists will study the biology of aging at the cellular level. They also will carry out research on clinical aspects of the aging process. The purpose is to develop pilot approaches to treatment and rehabilitation.

Among the clinical aspects are respiratory ailments, heart conditions, diabetes and other metabolic diseases.

Clinical studies will be conducted in a 12-bed research center at the VA Hospital. The center will be staffed by Stanford faculty and VA personnel.

Hollister and his associates will study drugs used to treat mental deterioration or senility.

Research will also explore treatment of the aged in different therapeutic environments.

In addition, the center will train residents in geriatric medicine, and organize postgraduate education courses for physicians in practice and other professionals.

The center will work closely and share information with local agencies, Hollister said.

The hoped-for result will be to facilitate the transfer of research results to clinical applications outside the VA system, he added.

Hollister has contributed toward understanding of drug abuse. He has pioneered patient selection methods and data analysis for clinical research with psychotherapeutic agents.

He is also the author of a definitive book on the subject. He has been on the Stanford faculty since 1953.

STANFORD--An endowed professorship in pediatrics has been established at Stanford University Medical School through gifts from Mr. and Mrs. Marron Kendrick of Atherton.

Dr. Clayton Rich, dean of the Medical School and vice-president for medical affairs, made the announcement for the University Board of Trustees.

"This new professorship, the second in pediatrics, joins 14 other endowed chairs at the School," said Dr. Rich. "It is an important gift which will immeasurably strengthen the future of pediatrics here, in teaching, in medical research, and in patient care."

The chair will be known as the Marron and Mary Elizabeth Kendrick Professorship in Pediatrics in the School of Medicine. Holder of the professorship has not yet been named.

The gift, the donors said, "Represents our statement of personal gratitude, for the exceptional and dedicated care received by our family from Stanford-trained doctors and the physicians, nurses, and staff of the Medical Center."

Kendrick is the chairman of the board of the Schlage Lock Co., headquartered in San Francisco, and a director of its parent corporation, Ingersoll-Rand. He received the AB in 1931 from Stanford in economics, and has been active over the years in Stanford affairs, serving as class agent, fund-raising volunteer, and currently as a member of the executive board of the Stanford Alumni Association.

Mrs. Kendrick, the former Mary Elizabeth Roth, is affiliated with the Stanford class of 1935, and is a member of the board of directors of the Children's Hospital at Stanford. The Kendricks have been particularly interested in perinatal and neonatal care, and have made substantial donations in the past for these purposes.

The Kendricks have extensive familial ties to the University. More than 25 close relatives and members of their immediate family have attended Stanford.

Mrs. Kendrick's father, the late Almon Roth, '09, JD '11, served the University as its first controller from 1919 to 1937. He had been the dean of men, 1909 to 1912, and later served as a trustee, 1940-43. As an undergraduate, he was a member of the track, football, and rugby teams, and was a charter member of Stanford's Athletic Hall of Fame. After leaving Stanford, he became known for his expertise in management-labor relations, and headed both the Pacific Coast and national shipowners associations.

Mrs. Kendrick's mother, Mildred Hayes Roth, received her AB from Stanford in 1911 in English. She is a member of Stanford Associates, and had long and distinguished service on the board of Children's Hospital at Stanford.

Kendrick's father, Charles, was a well-known San Francisco philanthropist. Besides extensive gifts to the University of San Francisco, he established a memorial scholarship fund at Stanford, in memory of Marron's brother, Charles W. Kendrick, killed in World War II.

STANFORD--"Coping with Stressful Experiences: Perspectives from a Collaboration with Alfred E. Weisz," will be the topic of the annual Alfred E. Weisz Memorial Lecture on Wednesday, May 12, at 8 p.m. in Kresge Auditorium of the new Stanford Law School building.

Speaker will be Dr. David A. Hamburg, Reed-Hodgson professor of human biology and professor of psychiatry at Stanford, and recently appointed president of the Institute of Medicine.

Members of the medical community, students, and the public are invited to attend.

The Weisz Memorial Lecture was established in 1970 to honor the late Dr. Weisz, assistant professor of psychiatry at Stanford. He had done research on the psychological aspects of population before his death from cancer in 1970.

Dr. Hamburg came to Stanford in 1961 as professor and chairman of the Department of Psychiatry and Behavioral Sciences. For 11 years he directed the department's development into a nationally recognized center of research on psychiatric problems.

In 1972 he stepped down from the chairmanship to develop new programs including the Stanford Laboratory of Stress and Conflict, the undergraduate Human Biology Program, and the Program on Science, Technology and Society. His research contributions have dealt with behavior under stress, especially hormonal responses and ways of coping with difficult situations.

FOR IMMEDIATE RELEASE

STANFORD –

Visiting hours in Stanford University Hospital's maternity areas have been reduced, the hospital has announced.

Although fathers may visit at any time, other visitors 16 years of age and older are now allowed only between 6:30 and 8 p.m. daily. Children under 16 may also visit during these hours, but they are restricted to the waiting area outside of the maternity unit.

State health codes require that children under 16 not be allowed on actual maternity patient units at any time, and hospital officials ask that children be supervised at all times.

Previously, visitors in maternity areas were also permitted from 3 to 4:30 p m. However, Lois Williams, assistant director of the hospital's Nursing Service, said this visitor period was eliminated to provide the nursing staff needed time for the teaching of patients on infant and personal care prior to their release.

STANFORD--Dr. Lewis Aronow, acting chairman and professor of pharmacology at Stanford University Medical School, has resigned effective Aug. 31.

Aronow, 49, will assume the chairmanship of the Department of Pharmacology at the new Uniformed Services University of the Health Sciences in Bethesda, Maryland. The school was established by Congress to train physicians for the military services and the Public Health Service. It will accept its first group of students in the fall.

Dr. Tag E. Mansour, professor of pharmacology, will be appointed acting chairman of the Stanford Pharmacology Department, succeeding Aronow.

A member of the Stanford faculty since 1956, Aronow is considered a national leader in his field. His research has centered on anti-cancer drugs, biochemical pharmacology and glucocorticoid hormones.

Aronow has also been active in teaching and faculty affairs in the medical school and at one time served as chairman of the admissions committee. He currently heads a committee which is completing a study of tuition policy in the medical school.

One of three co-authors of Principles of Drug Action, the Basis of Pharmacology, Aronow was a research fellow at Harvard University in 1955-56. In 1970-71 he served as an American Cancer Society-Eleanor Roosevelt International Cancer Fellow at Cambridge, England.

STANFORD--The Robert Wood Johnson Foundation has awarded a $65,300 grant to Stanford University Medical School in support of the planning of a research and training program in pediatrics.

The one-year study will help to determine if the primary health care needs of children are being met through current pediatric training. Researchers will then determine if combining traditional training with developmental psychology and behavioral training would lead to a new competency in pediatrics.

The study is under the direction of Dr. Ruth T. Gross, chief of the pediatric outpatient clinic at Stanford and director of the division of ambulatory pediatrics at Stanford Medical School. The co-investigator is Dr. Thomas F. Anders, head of child psychiatry at Stanford.

Part of the investigation will be conducted in cooperation with the Palo Alto Unified School District. John Martin, assistant superintendent for educational services says the study will involve a task force of classroom teachers, guidance and special problems counselors, health services personnel and administrators. Martin says, "We are working together because we are interested in the health of children. In the long run, the schools will benefit by being the recipient of healthier students."

According to Gross, in the past 25 years the problems seen by pediatricians have changed drastically. Infectious diseases which were once life threatening are now managed through immunization and antibiotic therapy. Today's pediatricians see a more complex set of problems related to behavioral or emotional disturbances. And traditional training may not prepare them to adequately deal with these problems.

The Stanford study, according to Dr. Gross, "will try to find areas where pediatricians would be able to intervene and improve the health of children if they were properly trained."

STANFORD--Stanford University Hospital has treated its 1,000th patient on the Coordinated Care Program (Co-Care), a multidisciplinary program designed to help restore patients' abilities to care for themselves.

Established in 1970 under the auspices of the Regional Medical Program, Co-Care was originally known as the Stanford Stroke Program and was designed to provide assorted hospital services for stroke patients.

Since then the program has expanded and is now designed to provide needed services for all patients with chronic or long-term physical or medical problems, according to Co-Care Nurse Coordinator LaVerne Westerlund.

Among the various hospital services brought in to help Co-Care patients are Physical Therapy, Occupational Therapy, speech therapy, social service and Discharge Planning. Others such as dietitians and hospital chaplains are also called in when needed.

Co-Care's 1,000th patient--Verneil Kuhfuss, 48, of Mountain View, Calif.--was placed in the program on his doctor's referral after suffering a stroke last April.

Like other patients receiving Co-Care services, Kuhfuss has received assistance in long-range planning for his future needs--an important element of the Co-Care program, Westerlund noted.

"These long-term needs involve selection of the appropriate 'next step' following discharge, such as a rehabilitation center, a skilled nursing facility, home care or out-patient care."

Westerlund, who has been nurse coordinator of the program since its inception, regards Co-Care as Stanford Hospital's "answer" to the absence of a geographical rehabilitation unit.

"It brings rehabilitative services to the patient, wherever he is in the hospital, keeping his individual needs in mind."

STANFORD--A claim for an unspecified amount against the architect who designed the new Stanford University Hospital wing has been made by the University, according to officials.

The claim concerns the hospital's first expansion phase, where total project costs have risen to $18.1 million.

The contract with the Texas firm of Caudill Rowlett and Scott calls for arbitration in such disputes, said Cassius Kirk, University staff counsel.

Kirk said the University contends that the building is not in accordance with what was anticipated. It seeks compensation because it feels the firm is responsible for the delays in the project and numerous problems in the building.

Work on the project began in Spring 1973, with completion expected in May 1975. Because of construction delays a new opening date was set for July 1976.

But last month Paul Hofmann, director of the hospital and clinics, announced that patients would not be placed there until December. The latest delay was caused by some functional deficiencies, but principally construction code violations noted by government inspectors in April.

Even before that inspection, however, Stanford had made a claim against the architect for a portion of the cost overrun.

According to original estimates, the cost of construction was $9.1 million, excluding activation costs and equipment.

That amount represented construction costs for two floors with 25 percent shell space for later completion, a basement that could be used as interim parking and the capability of adding a third floor in the future.

-more-

Included in the wing are 25 intensive care beds, and increased facilities for emergency services, cardiology, X-ray, surgical pathology, transfusion issue and coagulation, and postanesthesia recovery.

In 1974 the basic budget was revised to $12.6 million to cover design changes due in part to a new state earthquake law. A $2.4 million activation and equipment budget was determined, and $1.1 million, obtained in the meantime from private sources, was earmarked for completing a portion of the shell space for several departments.

But now, according to Hofmann, at least $2 million more will be needed to correct code violations, and to pay interest costs added by delays.

The building is financed by $6.3 million in federally guaranteed low interest private loans, and $6.3 million in private borrowing through the California Educational Facilities Authority, with the balance coming from hospital and medical school funds, and private gifts.

Dr. Clayton Rich, vice president for medical affairs, said the architect grossly underestimated the initial construction costs. Factors which the architect might not have taken into account were new stringent earthquake codes. Inflation also complicated the picture.

The architect was picked by a 10-member committee comprised of faculty, medical center and university planning office administrators. Records from that search show that Caudill Rowlett and Scott had designed or constructed some 30 hospital projects with over 2,000 beds--among them the Norton-Children's Hospital in Louisville, Kentucky, and Doctors Medical Foundation Hospital in San Antonio, Texas.

Several design errors in the new wing stand out. The building was originally designed to accept a third floor. But space developed to facilitate addition of mechanical and other support equipment for the extra floor is inadequate..

There are elevators in the wing which will not accommodate hospital beds, in addition to numerous code deficiencies and functional problems.

According to Emil C. Strom, health services planner at the hospital, changes are required among other things because of:

--bathrooms lacking facilities for the handicapped.

--sprinkler heads that hang too low into hallways.

--doors that are too narrow.

--stairwells with slippery surfaces, and handrails that are too short.

--lack of knee and foot controls in sinks where infectious materials are handled.

--stucco walls that are uncleanable for infection control purposes, and

--fire code violations.

Another deficiency is a 57-foot ramp connecting the operating rooms in the existing building to the recovery room and intensive care unit in the new wing. The wing has floor elevations different from the existing hospital, and ramps rising 3.5 feet have been built. Regulations require a level section every 30 feet.

Some surgeons and anesthesiologists have expressed concern that the ramp is too steep to safely transport anesthetized patients. In addition, they said, a bed, plus a patient and accessory cardiac support equipment weighs from 450 to 600 pounds, and may require more than two people to move it on the incline.

Jim McNally, director of facilities at the Medical Center, and Dr. Myer H. Rosenthal, director of the ICU, are now conducting tests on a similar ramp in the basement--without patients--to determine what changes will be needed to move the beds, and whether a hazard exists.

Original plans for the wing, according to hospital officials, had called for the new floor to be level with the old one. But an additional 3.5 feet of extra excavation would have been necessary before construction could have begun. To reduce costs, the excavation was not done.

-more-

444--Construction

Work is underway to correct the problems so that the building can be opened for patients in December. "The added space," Rich said, "is an absolute requirement, one that is long overdue. When the deficiencies are corrected, the building will be of undisputed benefit."

Meanwhile, the hospital has deferred hiring of new personnel for the wing. As many as 250 persons will be employed when the addition opens, about half of them are nursing personnel.

STANFORD--Stanford University School of Medicine awarded 145 degrees during its annual commencement exercises Sunday, June 13.

The ceremonies also honored six faculty members.

Medical degrees were presented to 73 men and women. The school also awarded 20 Ph.D's, 40 masters' and 12 bachelor of science degrees.

Diplomas were presented during ceremonies at Grant Courtyard at Stanford Medical School following the university's 85th annual commencement rites at Frost Memorial Amphitheater.

Dr. Clayton Rich, vice-president for medical affairs and dean of the medical school, and Dr. Hadley Kirkman, professor of anatomy, emeritus, presented the diplomas.

The guest address was given by Dr. Grady Stumbo, president of the East Kentucky Health Services Center and a primary care physician.

The Henry J. Kaiser Award for outstanding and innovative contributions to medical education was presented by Dean Rich to Dr. Ruth T. Gross, professor of pediatrics.

Michael D. Amylon, a member of the 1976 graduating class, presented the Henry J. Kaiser Awards for excellence in teaching to Drs. Michael B. Jacobs, assistant professor of ambulatory medicine; Mark Perlroth, senior attending physician and clinical associate professor of medicine; Eugene D. Robin, professor of respiratory medicine; and Lawrence H. Mathers, assistant professor of anatomy. Perlroth was awarded the honor last year as well.

For the second straight year, Dr. Daniel Federman, professor and chairman of the Department of Medicine, was presented the Arthur L. Bloomfield Award for recognition of excellence in teaching and clinical medicine. His award was given by Peggy A. Warth, a member of the 1976 graduating class.

A reception in the Dean's Courtyard for the graduates and their guests followed the convocation ceremony.

All but one of the medical graduates will receive additional clinical training in hospitals across the U.S. One graduate will undertake research work.

-more-

The 1976 medical school graduates and their hometowns:

CALIFORNIA--Raul Alvarez, Reedley; Michael G. Bazaral, LaJolla; Larry E. Bell, Palo Alto; Arnold Berk, Sherman Oaks; Edward P. Gelmann, Palo Alto; Fred E. Heidrich III, San Diego; Brian Lee Johnson, Arcadia; Alan M. Jones, Portola Valley; David T. Linker, Los Angeles; David Bruce Mark, Arcadia; Randall E. Morris, Hillsborough; Gary A. Palmer, Van Nuys; James D. Prickett, Palos Verdes Estates; Richard P. Rodriguez, Ontario; Martin Donald Rubenstein, Mar Vista; Paul M. Sanchez, Oxnard; Michael Lewis Shorenstein, Stanford; Rosalind Greenberg Shorenstein, Stanford; Edward H. Shortliffe, Stanford; Stephen Sidney, Palo Alto; Linda Skory, Berkeley; Suzanne Fields Steinbach, Stanford; Karen Johnson Train, San Francisco; James Pritchard Viney, West Covina; Lennard S. Wilson, Anaheim; Margaret J. Zwerling, Oakland.

RHODE ISLAND--Michael David Amylon, Scituate.

OKLAHOMA--Robert C. Barton Jr., Oklahoma City.

CONNECTICUT--Constance Bowe-Anders, Fairfield.

MINNESOTA--Barbara Covey, Minneapolis; David William Feigal Jr., Wayzata.

NEW YORK STATE--Nancy E. Ebbert, Syracuse; Sally Dorfman, Cornwall-on-Hudson; Ira Walter Gold, Brooklyn; Allen D. Hillel, Rye; Edward Lawrence Hoder Jr., Poughkeepsie; Arthur K. Huberman, West Hempstead; Joseph Magliozzi, Rochester; Leonard H. Sigal, Forest Hills; Owen Neil Witte, Stony Brook.

NORTH CAROLINA--Sanford Martin Dawsey, Chapel Hill.

PENNSYLVANIA--George G. Dougherty Jr., Shillington; Bruce P. Foreman, Pittsburgh; Robert H. Odell Jr., Wayne; Sandra Lee Propst, Honesdale.

TENNESSEE--Louis Martin Edelson, Memphis.

ARIZONA--Joseph Glassford Garner, Phoenix.

NORTH DAKOTA--Glenn Richard Gourley, Grand Forks; Kaarel T. Kaljot, Minot; Patrick George Lamb, Michigan.

STANFORD--Dr. Irving Schulman, an internationally known expert in childhood diseases and chairman of the Department of Pediatrics at Stanford University Medical School has been named Marron and Mary Elizabeth Kendrick Professor of Pediatrics.

The appointment was announced Friday, June 11 by Dr. Clayton Rich, vice-president for medical affairs and dean of the medical school. It is effective immediately.

Dr. Schulman, 54, came to Stanford in 1972 after serving as professor and chairman of the Department of Pediatrics at the University of Illinois College of Medicine from 1961-1972. He has also been a faculty member of the medical schools of Cornell University and Northwestern University.

Schulman is considered to be an outstanding investigator in pediatric hematology and has made significant research contributions in the fields of nutritional iron deficiency, hereditary hemolytic anemias, and disorders of blood coagulation.

One of Dr. Schulman's goals at Stanford has been the development of complete health care services for children. His efforts have resulted in closer ties with the Children's Hospital at Stanford and joint planning for patient care and pediatric academic programs.

Schulman was the recipient of the Mead Johnson Award for Pediatric Research (1960), the John F. Kennedy Award from Georgetown University for distinguished service to children (1968), and the Distinguished Faculty Award from the University of Illinois College of Medicine (1972). He was also elected president of the Society for Pediatric Research in 1967.

Born in New York, Schulman is an alumnus of New York University where he received his B.A. in 1942 and his M.D. in 1945.

He is the first person to hold the Marron and Mary Elizabeth Kendrick endowed professorship in pediatrics, which was established this year through gifts from Mr. and Mrs. Marron Kendrick of Atherton.

The gift, the donors said, "Represents our statement of personal gratitude for the exceptional and dedicated care received by our family from Stanford-trained doctors and the physicians, nurses, and staff of the Medical Center."

Kendrick is board chairman of the Schlage Lock Co., of San Francisco, and is a director of its parent company, Ingersoll-Rand. He received the A.B. from Stanford in 1931.

Mrs. Kendrick graduated with the Stanford class of 1935 and is a member of the board of directors of the Children's Hospital at Stanford.

STANFORD--Dr. Lubert Stryer, an expert on biologic structure and protein chemistry, has been appointed chairman of the Department of Anatomy at Stanford University School of Medicine, and holder of the Mrs. George A. Winzer endowed professorship in cell biology.

His appointment, which culminated a nationwide search, was announced Friday, June 11 by Dr. Clayton Rich, vice-president for medical affairs and dean of the medical school. It becomes effective July 1, 1976.

Dr. Stryer, 38, has been professor of molecular biophysics and biochemistry at Yale University in New Haven, Conn. since 1969.

He was on the faculty of the Department of Biochemistry at Stanford as associate professor from 1966 to 1969, and as assistant professor from 1963 to 1966.

The endowed professorship is named for Mrs. Frances Nunnally Winzer of LaJolla, Calif., a longtime major benefactor of the medical school.

Dr. Stryer is noted for his studies of biological structure at the molecular level, studies fundamental to a better understanding of cell organization and function.

His most recent work demonstrating the flexibility of certain components of an antibody molecule has provided new insight into the relationship between structure and function in an important class of protein molecules.

In addition to outstanding credentials as a scientist, he is considered an accomplished and stimulating teacher. His Biochemistry is a widely used textbook emphasizing principles of biologic structure and the interrelationship with function.

A native of Tientsin, China, Dr. Stryer received the B.S. with honors from the University of Chicago in 1957, and the M.D. magna cum laude from Harvard University in 1961.

He was awarded the Eli Lilly Award of the American Chemical Society in biological chemistry in 1970, and is a fellow of the American Academy of Arts and Sciences.

During his career he was a visiting investigator with the Medical Research Council Laboratory of Molecular Biology at Cambridge, England, and served as a consultant to the National Institutes of Health study section on biophysics and biophysical chemistry.

Dr. Stryer will succeed Dr. Lawrence H. Mathers, assistant professor and acting chairman of anatomy.

Mrs. Winzer's unrestricted gift of $2 million announced in 1974 will permit construction of a third floor in the Sherman Fairchild Center for the Neurosciences and help complete diagnostic and treatment laboratories in the new Hospital addition, in addition to the professorship. The Fairchild Center, scheduled for completion this year, will house the departments of neurobiology, anatomy and physiology laboratories for neurology and neuropharmacology, a bioengineering laboratory, and an auditorium.

EDITORS: The following story is released jointly by the National Council of YMCAs and the Stanford University School of Medicine.

STANFORD--A nationwide educational program aimed at lowering people's risk factors for heart disease is being developed by the Stanford Heart Disease Prevention Program and the National Council of YMCAs.

This is believed to be the first time that a prevention program of such wide scope has been established in respect to heart disease.

The Risk Factor Reduction Program will bring together the techniques developed in Stanford programs, notably the "Three Communities Study," with the nationwide staff and facilities of the YMCA.

Announcement of the program was made by Dr. John Farquhar, director of the Heart Disease Prevention Program at Stanford, and by Gary A. Fry, M.D., director of the YMCA's YMCArdiac Therapy Program.

The risk factor reduction classes are part of a broad cardiovascular health program being launched by the YMCA, with the aim of instituting health education and physical fitness activity centers throughout the nation. Another part of that program is YMCArdiac Therapy, which provides medically prescribed and supervised education and exercise.

The risk factor programs will be tested in three West Coast cities: Palo Alto, Portland and Los Angeles says Fry, and then implemented on a broad scale across the nation.

Stanford will develop the pilot programs, provide educational materials, assist in setting up the classes on Y premises, and train YMCA personnel--dietitians, nurses, health counselors and physical educators. Stanford personnel will act as consultants as the program is initiated more widely.

Classes being developed for the YMCA will be modeled after ones now being offered at Stanford facilities. These pilot programs deal with stress reduction; smoking cessation; and weight, diet and exercise control. They are open to the public, range from four to eight weeks, and involve eight to 16 sessions.

Dr. Farquhar lists recognized risk factors as smoking, high blood pressure, high blood cholesterol, emotional stress, and lack of exercise and obesity that play an important role in the early development of heart disease.

-more-

He notes that 80 percent of adult male Americans have at least one of the major risk factors, and 40 percent have two. Therefore programs aimed at reducing these risks, he feels should involve the entire community.

"Such programs, involving so many people of all ages, are beyond the scope of the current 'medical model' and require new community and family-based approaches at relatively low cost," he says.

He cites the groundwork laid for the YMCA program in the Stanford Three Communities Study, a three-year health education campaign conducted in three Northern California communities.

Large risk reductions were reported in communities receiving mass media educational campaigns and personalized instruction. There were also dramatic changes in people's knowledge about heart disease risk factors.

"That study showed that the average citizen has the capacity to increase his or her health knowledge and to take responsibility for improving health habits," says Farquhar.

ADVANCE FOR PM PAPERS TUESDAY, JUNE 1, 1976

EDITORS: Release date for this story has been set to coincide with the presentation scheduled for Tuesday afternoon, June 1.

STANFORD--Researchers at Stanford University Medical School have designed a computer-based consultation system to help physicians select antimicrobial therapy for their patients.

The MYCIN system (named for the many antimicrobial agents with that suffix) was discussed by Drs. Edward Shortliffe, Randy Davis and Stanton Axline of Stanford at the second annual workshop on "Artificial Intelligence in Medicine" at Rutgers University in New Jersey on June 1.

The MYCIN system has been under development at Stanford for the past several years. Researchers are still working to improve its performance, and do not expect it to be ready for general clinical use for some time.

MYCIN uses the computing facility of the Stanford University Medical Experimental Computer (SUMEX), established in 1974 as the first shared national computing facility for medical research. SUMEX is directed by Dr. Joshua Lederberg, professor and chairman of the Department of Genetics, and is funded by a grant from the Division of Research Resources, Biotechnology Resources Branch, of the National Institutes of Health.

The computer program is designed to determine if a patient has an organism which requires therapy, compile a list of possible therapies, and then determine the recommended one from that list.

It does that by "talking" via the keyboard of a computer terminal with the physician, asking questions, for example, about the patient's condition, available laboratory data, how the infection was acquired, just as a human consultant does.

The physician can also question the computer about its reasoning, even why it asks the questions it does, and how it arrived at its recommendations.

If the physician makes a simple spelling error in typing a question or answer, the computer will figure out what word was meant and correct the doctor's spelling. To some extent, the computer can also understand colloquial or everyday English expressions.

Researchers emphasize that MYCIN is designed to be a tool for the physician and not a replacement for his own judgment. The physician can ask the computer to justify both its questions and its final conclusions, so that the doctor may reject or accept its recommendations.

- more -

"We want the physician to be adequately assured that the computer knows what it is talking about," said Shortliffe.

The computer's reasoning power comes from "rules" that are programmed into it--rules based on the knowledge used by infectious disease experts. The more than 400 rules now in use were formulated during extensive discussions between the computer researchers and physician collaborators. New knowledge can automatically be incorporated into the program.

Currently researchers are testing the validity of the computer's judgment by comparing its recommendations with how several physicians would treat particular cases of bacteria in the blood.

According to Shortliffe, "We expect the program will be ready for introduction once the experts approve its performance in at least 90 percent of cases, or once they agree with MYCIN's reasoning as much as they agree with each other."

Shortliffe said his reasons for developing the MYCIN system stem from studies that have shown a need for improved drug selection for patients with infectious diseases. Since the advent of penicillin and streptomycin and other antimicrobial agents, he says, almost one-third of patients in an average general hospital are receiving at least one such agent on any given day, with wide opportunity for indiscriminate use or misuse.

The computer system also allows for immediate initiation of therapy, he says, without the need to wait for final results of laboratory cultures for a patient who may be critically ill.

Shortliffe began work with the computer project as a medical student in the laboratory of Dr. Stanley N. Cohen, professor of clinical pharmacology at Stanford. Drs. Cohen and Axline are coprincipal investigators in the research which is supported by grants from the Bureau of Health Services Research and Evaluation of the Department of Health, Education, and Welfare.

Davis is a Stanford graduate student in computer sciences. He completed doctoral research on the problem of allowing MYCIN to learn directly from infectious disease experts who need not understand computer programming.

STANFORD--Pianomime, a nonprofessional mime troupe that includes several Stanford students and staff members, will present a benefit performance Wednesday, July 28 starting at 8 p.m. in the Little Theater on campus.

Proceeds from the event will go to the Premature Research Center at Stanford University Hospital.

Formed last fall, Pianomime is a seven-member troupe directed by Stella Bensadon, who is an instructor in mime. A former student of Ella Jaroszewics (ex-wife of legendary mime performer Marcel Marceau), Bensadon taught mime in 1966-67 at Stanford and in 1975-76 at San Jose State. In 1974 she was instructor to a Stanford troupe called "The Company."

In addition to Bensadon, other Pianomime members are Jill Hester, Helene Davis, Jeff Cabili, Beccy Sako, Scott Daniels and Clyde Dodge. The troupe is accompanied musically by Bob Willey, a music major at Stanford, who plays both piano (from which the troupe name is derived) and the guitar.

In addition to its upcoming performance on campus, Pianomime also recently performed at Cubberley High School in Palo Alto and at San Jose's Bicentennial observance.

Tickets may be purchased at the door.

STANFORD--David Rand Charney, 23, a graduate student in biochemistry at Stanford University Medical School, was found dead in his home at 1196 Hamilton Avenue, Palo Alto Tuesday evening, July 20, apparently from gun shot wounds.

According to the report of officer Bryan Chiles of the Palo Alto Police Department, Charney's brother, Allen, of Wheaton, Maryland, had been talking with Charney by telephone when he heard gun shots, and called the police to investigate.

The cause of death is being investigated by the Santa Clara County Coroner's Office.

Charney was in his third year of graduate work in the department of biochemistry. He had received his undergraduate degree in biochemistry from Columbia University, and entered Stanford in September 1973.

In addition to his brother, he is survived by his parents, Mr. and Mrs. Louis Charney of Las Vegas, Nevada.

STANFORD –

"If doctors devoted as much time and energy to minimizing the need for medical care as they now devote to its delivery, the quality of life might increase appreciably."

This is the opinion of Victor Fuchs, professor of economics at Stanford University, writing in the July issue of ***The Western Journal of Medicine.***

"One step is the development of self-care, including care by family and friends," says Fuchs. "Self-care movements are burgeoning, both in this country and abroad.

"To be sure, some of them are simply fads, some are gimmicky, and some may be dangerous frauds.

"At their best, however, they are attempts to give concrete expression to what every physician knows: an intelligent, informed lay person can deal with a large proportion of the acute and chronic conditions that are called illness.

"The trickiest part is making sure that such conditions requiring professional attention get it promptly."

Fuchs, who is a vice-president of the National Bureau of Economic Research, maintains that beyond encouraging and teaching self-care, medicine could contribute to the quality of life by the promotion of health.

This is not easy, he admits, since much that affects medicine is beyond its reach. Many doctors are moving in this direction, he says, but more could be done.

"Medical schools in particular," says Fuchs, "could increase the emphasis on the prevention of disease and the maintenance of health in their research and teaching.

"A physician emerging from a school with this emphasis would take a broad view of his duties and responsibilities. Instead of the yardstick of success being the length of the queue in the waiting room, physicians would judge themselves collectively by improvements in the health levels of the populations they serve."

Fuchs warns that people should not have unrealistic expectations of medicine, and doctors should not promise more than they can deliver.

"The quality of life depends on many things besides health," he writes, "and health depends upon many things besides medical care. But given medical care's share of the gross national product (over 8%), significant improvements in our health system could have major spinoffs for other sectors."

Fuchs says that medicine has made important contributions to raising life expectancy and has contributed to a fuller, more satisfactory life for millions.

But its advances, associated with increased specialization, have had their negative aspects also.

"Many of the advances and (pseudoadvances) have been very expensive," the economist says. "Each additional reduction in mortality or morbidity requires a massive diversion of resources from other purposes.

"Some technologic advances, which are viewed not so much as extending life as prolonging dying, may actually adversely affect the quality of life."

Fuchs recommends that leaders of medicine should eschew taking bows for contributions of the past, abandon the myths that presently enthrall teaching and practice, and create a more effective and equitable system of health care."

SCIENCE WRITERS: The following story is distributed jointly with the University of California, San Francisco

STANFORD –

Stanford University and the University of California have filed an application to patent key elements of a new genetic engineering technique developed by scientists at both institutions.

If awarded, the patent would cover commercial use of the process, said Niels Reimers, manager of Stanford's technology licensing program. It would not affect its use for academic or industrial research.

Reimers said licensing of the patent by Stanford and UC would help enhance early use of the beneficial aspects of the technique. It would also require commercial users to abide by safety guidelines issued recently by the National Institutes of Health.

The guidelines, which apply to federally funded research only, ban hazardous experiments and allow others under strict physical containment procedures.

Stanford and UC, according to Reimers, will be entitled to royalty income only if the process is used commercially. The money will be applied to further education and research.

However, William F. Massy, acting vice-president and provost, stressed that Stanford has made no decision to exploit the technique commercially. "The matter is still under discussion with federal officials, and being debated internally," he said.

The technique was developed by groups headed by Dr. Stanley Cohen of Stanford and Dr. Herbert Boyer at the University of California, San Francisco. They published their findings in 1973 and 1974, and it was their research which opened an unprecedented public debate of possible risks and benefits in the experimental manipulation of genes.

The method permits the transplantation of genes from one organism into another. It has the potential of creating a wide variety of novel genetic combinations in microorganisms.

Although the process is important in molecular genetics for the study of medical problems, it also makes it possible to introduce genes into easy-to-grow bacterial cells. This potentially enables construction of bacterial "factories" that will synthesize a variety of biologically produced substances such as insulin, hormones and so on.

Such commercial uses would be covered by the patent.

Cohen and Boyer have stated that neither they nor other scientists named in the application would benefit financially if the patent is awarded. They have made personal decisions to assign their proceeds to fellowship programs and research.

The scientists' work was funded by the NIH, the American Cancer Society, and the National Science Foundation. These agencies have agreed that the work could be handled under the institutional patent agreement of Stanford with NIH. The agreement gives universities sole patent rights to inventions developed with NIH support unless a project is specifically exempted. The genetic studies were not.

Scientists believe the technique is a landmark technical achievement with enormous potential for medicine and agriculture.

But they also have been concerned that such techniques could be used for construction of novel gene combinations that may be hazardous to humans.

In 1974 a committee of the National Academy of Sciences called for a temporary deferral of certain types of experiments until the potential risks were fully assessed.

The review culminated with the publication of the long-awaited guidelines by the NIH last month.

STANFORD -- A new experimental therapy for psoriasis, combining oral drugs and ultraviolet light, could become the most effective treatment for this disease, dermatologists report.

But they also cautioned against its widespread immediate use until current studies can measure risks as well as benefits.

Oral psoralen and ultraviolet-A (PUVA) photochemotherapy is being evaluated in clinical trials with more than 1,000 patients in 16 U.S. medical centers, including Stanford. It is reported to have more than 90 percent effectiveness in clearing psoriatic skin disease.

Scientists reported at the Second International Symposium on Psoriasis being held this week at Stanford that "there are no known medical problems associated with PUVA." However, they reported concern about possible long-term delayed hazards, such as skin cancer or cataracts.

The benefits of the new treatment include more rapid clearing of skin lesions than with other existing treatments, without the daily laborious applications of ointments, or use of more toxic drugs.

"There would be virtually no restrictions of a patient's job or his life style," say Drs. Thomas B. Fitzpatrick, John A. Parrish, Madhukar A. Pathak, and Lewis Tannenbaum, all of Harvard Medical School and Massachusetts General Hospital, who were among the symposium participants.

The average patient on PUVA therapy, who has at least 30 percent of his body involved in the disease, is cleared of psoriasis in 15 to 20 treatments, given twice weekly. Each treatment requires less than 15 minutes. After clearing, weekly treatments of 15 to 25 minutes may be required.

The risks, according to the Harvard team, "are theoretical long-term effects, as there are no acute toxic effects in more than 1,650 patients now under treatment." They have not observed any evidence of serious injury to the eye, liver, skin or any other organ.

- more -

Some researchers say the skin and eyes could be the targets of adverse effects delayed over many years.

In the therapy, the drug Methoxsalen is taken by mouth. It acts as a photosynthesizer, sensitizing the skin to light. Then the combination of drug and special ultraviolet light treatment appears to slow down and break up the disease process.

In the presence of ultraviolet light, the drug binds to DNA, the genetic material of cells, affecting cell function by decreasing DNA replication and cell division. In psoriasis, the regulatory mechanisms that control cell reproduction are impaired; the cells multiply much more rapidly than normal, causing thick and scaly skin.

The drug Methoxsalen is not approved for use in this regimen except experimentally, and an approved ultraviolet light system is not commercially available.

Drugs such as Methoxsalen, called psoralens, have been commercially available for use in other skin diseases for more than 20 years, without adverse effects, say the Harvard researchers, except for burning or blisters that may occur without careful use.

Psoralens are present in eatable plants, they say, and have been used since ancient times in medicines. But studies in animals have shown that prolonged exposure to very high intensity ultraviolet light has caused cataracts, especially when the drug is given also.

Dr. Eugene Farber, chairman of the department of dermatology at Stanford University Medical School, and moderator of the symposium discussion, said patient demand for the therapy has been very high. Current use of PUVA, he emphasized, is "promising" but strictly experimental, and more widespread use should await guidelines that will come from the nationwide study.

Current experimental trials with PUVA, which began in May 1975, are continuing, and patients will be followed for the next five years to determine the safety of the treatment.

FOR IMMEDIATE RELEASE

STANFORD –

Day-care therapy for severe cases of psoriasis has been effective in 80 to 90 percent of cases, according to reports from physicians at both Stanford and UC-San Francisco medical centers.

The first such day-care centers in the country, opened in 1974, enable patients to receive treatment during the day and return to their families each evening.

Between 80 and 90 percent of 204 patients with severe psoriasis remained clear of the disease for a year or longer after treatment at the Stanford center, according to Dr. Eugene Farber, professor and chairman of dermatology, and Dr. William Watson, assistant professor of dermatology.

Dr. David L. Cram, director of the UC center, presented similar findings using somewhat different therapy. The reports were made at the Second International Psoriasis Symposium being held this week at Stanford University.

Psoriasis, a common skin disorder that causes itching, scaling and redness, affects six million people in the U.S. While no permanent cure is yet known, various treatments with salves or ultraviolet light provide effective control.

According to Dr. Farber, the day-care centers were designed to meet the need of patients who cannot afford to spend time away from their families or jobs for hospital treatment, yet find it difficult to care for themselves adequately at home.

Most of the patients treated at the Stanford center had 50 to 75 percent of their bodies involved, with lesions too extensive to treat at home, says Dr. Watson.

Patients receive individualized treatment which may include ultraviolet light, medicated baths, and applications of various preparations. Anthralin paste has been in use at Stanford, which has an advantage of providing rapid clearing of lesions, according to Dr. Watson. Therapy at UC involves the use of coal tars, a long-time effective treatment for psoriasis.

Stanford patients report to the center in the morning five days a week for therapy sessions lasting seven or eight hours. The average treatment program lasts about 10 days.

While under treatment, patients have access to a sun parlor and special lounges where recreational and occupational therapy is available.

A recent addition has been psychiatric group therapy sessions. According to Dr. Watson the sessions with dermatologists and psychiatrists have proved very effective in helping patients achieve a positive outlook about their disease and better manage when they go home.

In addition the program reduces the cost of hospital treatment, says Dr. Watson.

The Stanford and UC centers were the first of only a few centers now in the U.S.

STANFORD--Swimming and sunbathing at the Dead Sea may be an effective treatment for psoriasis, according to a report by Dr. Willy Avrach of Hadassah University Hospital's Dead Sea Psoriasis Center in Ein Boquk, Israel.

Avrach, medical advisor to the Royal Danish Embassy in Israel and a noted skin specialist in charge of the center, reported his findings Wednesday, July 14 at the Second International Symposium on Psoriasis at Stanford.

According to Avrach, "96 percent of the patients were either free of symptoms or had obtained improvement" after treatment consisting of rest, bathing in the sun and the Dead Sea, application of bland emollients to the skin, and patient education.

Conditions at the Dead Sea are unique for this type of therapy, although climatotherapy is available in other countries including Yugoslavia and Bulgaria.

Because the Dead Sea is the lowest place on earth--1286 feet below sea level--patients spend up to seven hours in the sun without burning as the ultraviolet rays which cause sunburn only rarely penetrate the area's high density air.

In addition, the sea's mud "probably contains a photosensitizer" which aids in treatment, according to Avrach. Although patients spend more than an hour in the sea daily, it is not known how the water's high salt and mineral content contribute to the therapy.

According to Avrach's report, of the 1052 patients treated for four weeks from 1971-1975, 24 percent were "completely clear" of symptoms after therapy; 53 percent showed "marked improvement"; 19 percent "partial improvement"; and only 4 percent had no change, deteriorated, or did not complete the treatment. After returning home, 45 percent reported recurrences within one month, but 65 percent observed the recurrences were milder than after previous hospital treatments.

An important part of the therapy may be the vacation atmosphere of the Dead Sea area and the rest and relaxation that are encouraged, according to Avrach Some scientists feel stress is related to psoriasis, and the therapeutic atmosphere may play a significant role.

STANFORD--"The influence of life stress, emotional disorder and personality type has been grossly exaggerated" as causes of psoriasis according to Drs. Richard D. Baughman and Raymond Sobel of Dartmouth Medical School.

The doctors presented their findings on the possible causal relationship between emotional state and psoriasis Tuesday, July 13 at the Second International Psoriasis Symposium at Stanford University.

Psoriasis, which affects an estimated six million people in the United States alone, is characterized by red patches covered with white scales that cause itching.

Baughman, a dermatologist, and Sobel, a psychiatrist, conducted a controlled study over a six-month period which included testing with a standardized psychiatric questionnaire and psychiatric evaluations of 48 hospitalized psoriatics and a larger control group.

They found the psoriatics were, if anything, better-adjusted than the control group and there was "no evidence of a psoriatic personality type or of any psychological or psychosocial predisposition to the disease."

Many doctors and patients feel there is a connection between psoriasis and emotional factors and that the disease is aggravated by stress, but Baughman and Sobel conclude that if such a connection does exist, "it has been grossly exaggerated. This is perhaps a result of the need to provide a plausible explanation for an otherwise inexplicable illness which affects millions of persons," they said.

STANFORD--Scholars from 27 countries gathered at Stanford University on Monday, July 12, for a week-long symposium about psoriasis, a common skin disorder suffered in nearly all parts of the world.

Dr. Eugene Farber, professor and chairman of the department of dermatology at Stanford School of Medicine, delivered the opening address at the Second International Symposium on Psoriasis. He called for more research on many fronts, including the search for a viral cause of the disease, and study of psoriatics' immunity systems.

More than 200 dermatologists and skin disease researchers at the symposium will discuss topics ranging from newest treatments to immunology, hereditary aspects, and the biologic nature of the disease.

Psoriasis, which affects an estimated six million people in the United States alone, is characterized by red patches covered with white scales that cause itching. The degree of severity varies from patient to patient. Some have only patches on their elbows, knees and scalp; others have their entire body involved.

Man's outer skin, the epidermis, is composed of layers of cells, which are continually being reproduced and shed. In psoriasis the regulatory mechanism for this is impaired and the cells multiply much more rapidly than normal. As a result the skin becomes thicker and scaly.

The disease is not contagious. What causes it is not known, and there is no permanent cure. Treatments for disabling cases can include potent drugs, ultraviolet light therapy, and ointments applied to affected areas.

Dr. Farber foresees major advances both in treatment and in investigations of the origin of the disease within the next five years.

He feels there should be a concerted effort to consider a viral cause of the disease, although he notes that as yet "there is no hard evidence for presence of a virus."

- more -

He speculated that a search for the cause of psoriasis should include a search for a "slow virus." A slow infection is caused by an agent that continues to multiply over months and years, producing changes in a single organ up to a year or more after it is contracted.

Immunology is another area Dr. Farber says deserves intensive study. "A direct approach for a psoriasis-specific antigen would be fruitful," he says. "There are subtle signs that psoriatic patients show somewhat suppressed cellular immunity while they may be hyperproducers of antibody."

Establishing a non-human host for the disease should also have a high priority, he said. There are no satisfactory experimental models, he said, and that is a serious handicap to research.

"The ideal model would be classical psoriasis in a non-human primate," he offered. Psoriasis has never been diagnosed in any animal species, though non-human primates have nearly every other disease known to man.

Dr. Farber foresees more applications of basic principles from other disciplines, including virology, genetics, immunology, and pharmacology.

"Where the main area of progress will be is something we can't predict at this time," he said. "We cannot assume that there is a single road that will lead to the discovery of the cause and cure of psoriasis."

He foresees improved therapeutic systems, and less toxic chemotherapy. Investigations of the basic mechanisms of skin cell growth and metabolism are paving the way for more effective treatments.

STANFORD--Dr. Howard Cann, Stanford associate professor of pediatrics and genetics, is one of a group of doctors serving on an advisory committee to the newly-formed genetics disease control unit of the State Department of Health.

Cann, and the other committee members from the state's medical schools, are charged with recommending tests for newborns to be required under the new genetics testing bill (SB 489), passed into law by the legislature last September. The bill will probably be implemented early in 1977.

At present, the state only requires testing for one genetic disease--phenylketonuria (PKU). Of the 300,000 babies born in California each year, about 20 will have PKU, which leads to severe mental retardation if not treated early with a special diet.

But there are other genetic diseases which, although less common, can be as debilitating as PKU. Some of these diseases can be detected through testing in the newborn period and treated, and the law will make these tests mandatory.

Cann feels the committee will only recommend tests for diseases which have an effective treatment. "It is not enough to have a test which will accurately pick up a disease and can be implemented easily," he says. "There's also got to be a treatment for the disease. If you can't treat a disease, or offer some other positive alternative such as prenatal diagnosis, there's no need to screen newborns for it."

The law, signed by Governor Brown last year, establishes a genetics disease unit "to coordinate all department programs in the area of genetic disease and to promote a statewide program of testing information and counseling services."

The law requires that tests for six genetic diseases--galactosemia, histidinemia, galactokinase deficiency, homocystinuria, maple syrup urine disease and tyrosinosis--be evaluated by the genetics disease unit which will consider the recommendations from its advisory committee of doctors. Cann says screening for two or three disorders will be recommended in addition to PKU. They are congenital hypothyroidism, galactosemia, and maple syrup urine disease. The other diseases are either extremely rare, have no good screening test available for the newborn period, or there is some controversy as to effective treatment.

- more -

Hypothyroidism, a deficiency in thyroid function, affects as many as one in 7,000 babies and can be treated with thyroid hormone. Unchecked, it can cause extreme mental and growth retardation.

Galactosemia is a relatively rare disease which strikes only one baby in 100,000. But it has an extremely common trigger--milk. The infant is unable to digest galactose, a component of milk sugar, and after the first few feedings can show symptoms of the disease. If diagnosed, a diet free of milk sugar is prescribed.

Maple syrup urine disease is the rarest of the group, with only one case in 200,000. It is a metabolic disorder in which breakdown products of three amino acids accumulate in the blood, urine, cerebrospinal fluid and various tissues of the body and affect the central nervous system. Because it occurs rarely and the effectiveness of the treatment is still unevaluated, Cann feels the advisory committee may recommend this test not be included.

Cann estimates that the cost for these tests should not exceed the $5 currently charged for the PKU test alone by most hospitals. The tests will be required for all newborns in California, except on grounds of religious conflict.

Although only three or four tests are likely to be recommended, more can be added to the list as effective tests and treatments are developed. "We will continually be reviewing the data on how effective these tests are, how effective treatment is, and the frequency of the disease's occurrence in the population," says Cann.

EDITORS: Copies of The Healing Arts are available upon request if not included.

STANFORD--Twenty years ago, Sandy Kolterman was an eight-year-old on vacation with her family when she suddenly developed symptoms of juvenile diabetes.

Today she is an aware, intelligent and attractive woman. She is also legally blind. As a rehabilitation therapist at Palo Alto's Peninsula Center for Blind and Visually Handicapped, she helps other people who are blind as a result of diabetes to cope with their unique problems, as well as working with people who have lost their sight for other reasons.

Kolterman is featured in the current issue of The Healing Arts, a publication of Stanford University Medical Center. The entire issue deals with diabetes, a disease in which the body is unable to burn carbohydrates efficiently because of an insufficient amount or lack of insulin.

Early in this century, insulin-dependent diabetics could only hope to live a few years after the onset of the disease. Today, though, with insulin injections and diet, most diabetics can lead fairly normal lives. Complications from diabetes, however, evolve over a long time, and because diabetics now live longer, they run a higher risk of experiencing some complications, one of which is blindness.

Diabetic retinopathy is the leading cause of blindness in people under 60 in the United States today. It involves the blood vessels of the retina which become weak and leak blood or other fluid into the retina, ultimately destroying vision. There is no cure for the disease, although Stanford ophthalmologists and others are successfully treating it and help to prevent total loss of vision through the use of argon laser therapy which destroys the weak blood vessels before they can hemorrhage.

Kolterman, who lost most of her sight as a result of diabetic retinopathy, is incredibly well-adjusted and she only feels discouraged that "there still isn't sufficient public education about the disease. My parents were well-educated and informed people, yet none of us knew there was a possibility I would lose my sight."

She credits them with her smooth adjustment to the disease. "My parents educated me about diabetes and taught me to take care of myself. I was administering my own injections by the time I was ten." Her life was kept as normal as possible, and she was told, "Now get out there and play football, but be sure to carry a candy bar with you."

-more-

Kolterman was aware that she was different from her peers and says, "A juvenile diabetic is the kid who has to have a shot every day, and has to have different activities on the playground. Some children have insulin reactions after they're first diagnosed. Until they learn to handle it, they may pass out on the playground or act 'funny' and the kids think they're drunk. So there are a lot of psychological implications."

Kolterman had a "normal" adolescence and says, "The only thing I resented, is that I couldn't do all the things my friends did. When everyone else started drinking beer I was scared to death and never touched it."

It was at college, at age 20, that she first began having trouble with her sight. "I was shooting archery and noticed a 'floater.' It was my first hemorrhage. I kept trying to brush this spot away, and after a few days it hadn't gone away and began to affect my shooting. I went to an ophthalmologist, he examined my eyes, and said I had diabetic retinopathy. Within six months I lost all the sight in my left eye."

Undaunted, she returned to school with total vision in only one eye. "I was back two weeks when in the middle of taking a shower I had a massive hemorrhage in my good eye and was totally blind except for shadow perception for about two weeks." Her condition stabilized and she now has 20/160 vision in the lower left quadrant of her right eye and is totally blind in her left.

Once her condition stabilized, Kolterman learned to cane travel, was taught braille, and returned to college. She was the first blind student to earn a master's degree in education at Stanford University, but says, "No one wanted a blind English teacher, even though I have some vision."

Kolterman was offered a job as a rehabilitation therapist for the visually handicapped and decided to draw on her own experiences to help others. Her ability to cope serves as a reassuring example to them even though most of the diabetics who are referred to her are distraught because they fear that they can no longer take care of themselves.

"They'll be sent over here in a panic because they can't imagine how they'll be able to give themselves an insulin injection or test their urine. I spend a lot of my time counseling and teaching them about special devices available to help them."

One of these is a card which attaches to a syringe and helps the diabetic to measure his correct insulin dosage. Another is a metal cap which fits over the insulin vial to guide the needle into it. Kolterman is aware of these and other products designed to aid diabetics with low vision.

Sandy Kolterman is a woman who lives very much in the present. Although she has not experienced any other complications from her diabetes, she is realistic about living with a disease that will not go away.

FOR IMMEDIATE RELEASE

STANFORD –

Registered nurses at Stanford University Hospital represented by CRONA (Committee for the Recognition of Nursing Achievements) have signed a new two-year contract with the Hospital providing an eight percent wage increase effective immediately, and an additional seven percent adjustment effective July 1, 1977.

The Hospital and CRONA jointly announced the agreement on Wednesday, June 30 following four months negotiations. CRONA represents approximately 900 full and part-time nurses employed at the Hospital.

Under the new compensation provisions, a new employee will start at the staff nurse I level earning $1,081 per month. The previous rate was $1,001.

Additional provisions of the new contract include changes in the Hospital's dental, educational and retirement plans.

Paul Hofmann, Hospital director, said the negotiations were conducted "with a mutual sense of cooperation." Negotiating committees reached final terms in lengthy sessions last weekend, and nurses voiced near unanimous approval in ratification meetings Monday.

Two years ago registered nurses at the Hospital were on strike for 11 days before settlement was reached.

Representing the Hospital on the negotiating team were Margaret Neill, Joe Ross, Carol Sasso, John Schwartz, Ron Twomey, and Carol Ann Hoshour. CRONA was represented by Marilyn Barnes, Mary Boudeman, Donna Gaffri, Margo Isola, Joan Kuykendall and Peter Fortune.

FOR IMMEDIATE RELEASE

STANFORD :

C

William E. Ayer, Stanford University trustee, has been named chairman of the Stanford University Medical Center Council, a recently established organization that coordinates fund raising and volunteer activities at the Medical Center.

Ayer is founder and former president of Applied Technology in Sunnyvale, and is present chairman of the board of Develco Inc. in Mountain View. His appointment to the Medical Center Council was recently announced by Dr. Peter S. Bing, president of the Stanford University Board of Trustees.

As chairman of the Council, Ayer will also serve as chairman of the Committee on Resources of the Medical Center, a group of volunteers who will help meet funding needs for new facilities, renovation and expansion of current facilities, as well as for research, patient care, and teaching programs.

Ayer is a member of the boards of directors of Barry Research Corporation of Palo Alto, Buckbee-Mears Company of St. Paul, California Water Service Company in San Jose, Commerical Electronics Inc. in Mountain View, Electrofusion Corporation in Menlo Park, GRT Corporation in Sunnyvale, and Spectra-Physics Inc. of Mountain View. He is a trustee of the Palo Alto Medical Research Foundation.

Ayer holds four Stanford degrees, the A.B., A.M., E.E., and Ph.D. He was elected to the Stanford Board of Trustees in 1974, and is a member of Stanford Associates, the Advisory Council to the School of Engineering, and the Northern California Major Gifts Committee for the Campaign for Stanford.

He and his wife, Mary, reside in Los Altos Hills. Their three sons are Stanford graduates.

FOR IMMEDIATE RELEASE

STANFORD –

Stanford University Hospital charges will increase an average of 11 percent in the new fiscal year starting September 1.

The new rates, according to Paul Hofmann, director of the Hospital and Clinics, are necessitated by increases in wages and benefits and in the costs of medical supplies and utilities.

"Another significant factor," Hofmann said, "is that the Hospital will be employing more personnel to keep up with advances in medical technology and increases in the complexity of illnesses treated here."

The hospital board of directors voted on Tuesday, August 17, to approve the annual budget, including room rate increases averaging 12 percent. Ancillary services such as X-ray, laboratories, and pharmacy will be increased an average of 10 percent.

Medical and surgical patients will be charged $134 for ward accommodations, $146 for a semiprivate room, and $165 for a private room. As in past years, rates for medical and surgical patients utilizing the services of house staff physicians (interns and residents) are $12 higher for each type of room. The patient's attending physician determines the medical need for house staff services.

Hofmann pointed out that the new rates compare favorably with those charged by similar highly-specialized teaching facilities. He also noted that more than 98 percent of the hospital's funds come from patient revenues. The hospital has no tax support or endowment income.

"Our approach to pricing our services in the past few years has been to see that the price for each service more closely reflects the cost of providing it," Hofmann said. "Historically, most hospitals undercharged for some services and overcharged for others. Stanford University Hospital and many others are moving away from this practice. That is why room rate increases are slightly larger than those for ancillary services," he said.

Hofmann said that only a small part of the increased rates is related to the cost of starting up the new hospital wing now under construction and scheduled for occupancy in 1977.

"The new facility should be basically self-financing after the first year of operation and maybe sooner," he said. Rates in the new facility will be identical to those in other parts of the hospital. The new construction increases bed capacity from 618 to 643 and improves the capacity of several ancillary services.

The last increase in daily room rates was a 2 percent rise in November 1975, for the purpose of covering an almost $1 million increase in the Hospital's annual malpractice insurance rate.

STANFORD--A proposed "natural death act" now under discussion in the California Senate, "would allow a patient to make an informed decision about the quality of life he or she wishes to maintain," according to Paul Hofmann, director of Stanford University Hospital and Clinics.

The bill (AB 3060) would legally recognize the right of an adult to direct his physician, in writing, to withhold or withdraw life-sustaining procedures in the event of a terminal condition.

Hofmann endorsed the bill in testimony prepared for the Senate judiciary committee hearing Tuesday, August 17, 1976, saying "with its safeguards, a patient will not have to abdicate this fundamental prerogative to health care providers, relatives or others."

The legislation would allow a person to decide, in advance, whether medical care should be withheld or withdrawn in the event of a terminal illness or mortal injury.

The bill defines a life-sustaining procedure as one which utilizes mechanical or other artificial means to sustain a vital function to prolong the moment of death where, in the judgment of the attending physician, death is imminent.

It does not authorize mercy killing, and does not permit any deliberate act or omission other than to permit the natural process of dying.

Under its terms physicians, other health professionals and health facilities would be relieved from civil liability or criminal prosecution for withholding life-sustaining procedures at the patient's request.

The directive would not prevent life-saving techniques from being used. Rather, says Hofmann, it would be a guide at the "frequently obscure point in the continuum of medical treatment when it is death, not life, which is being prolonged."

Currently, says Hofmann, physicians, family members, clergy, and occasionally patients, jointly decide the course of treatment or nontreatment, including the decision to withhold or withdraw mechanical respirators or other such equipment.

He cited problems raised by the "technological imperative"--the use of life-sustaining methods because they are available.

"The answer," says Hofmann, "lies in compassionate action which will relieve the terminally ill patient of unnecessary pain and suffering--action approved by the only individual truly qualified to do so. Only then will patients remain the beneficiaries of modern technology and not its victims." ###

STANFORD--Margaret LaVanne Denley, 55, of Los Altos, wife of Terence W. Denley, associate general secretary for Stanford and associate director of development at the Medical Center, died on Saturday, August 7, 1976 during a vacation trip with her husband to Honolulu. She had been ill for more than a year.

Trained as a bookkeeper and public accountant, Mrs. Denley worked in that capacity for a number of local organizations, including the Stanford University Accounting Office, Philco Corporation in Palo Alto, the First Presbyterian Church of Palo Alto, the Menu Tree Restaurant, and the Ladera Oaks Swim and Tennis Club.

She was a member of the parish of St. Nicholas Church, Los Altos, the Los Altos Women's Club, and the Stanford Faculty Wives Club. Before her illness, she was an active golfer and a member of the Stanford Women's Golf Club.

Besides her husband, she is survived by her mother, Mrs. Bessie Bumps, a half-sister, Mrs. Merle Driver, both of Santa Cruz; and three children, all of San Jose, Roger Frank Carr, Mrs. Donna Denise Sowers, and John Thomas Carr. She had five grandchildren.

A rosary will be said at Spangler Mortuary in Los Altos on Thursday, August 12, at 8 p.m. A memorial mass will be held on Saturday, August 14, at 10 a.m. in St. Nicholas Church.

The family suggests that memorials be directed to cancer research at Stanford University Medical Center.

STANFORD--Twenty-four local children have volunteered to spend part of their summer sleeping to help research at a unique sleep camp at Stanford University.

The youngsters are participants in a study of the sleepy child and related learning problems directed by Drs. William C. Dement, professor of psychiatry and behaviorial sciences, and Thomas F. Anders, head of child psychiatry at Stanford University Medical School. The study is funded by the Spencer Foundation of Chicago.

"Excessive daytime sleepiness," says Dement, "is believed to have a damaging effect on learning and school performance." He finds that some children have been diagnosed as mentally retarded while their sleepiness was overlooked.

Six groups of four children, aged 9-13, are participating in the sleep disorders study. All are volunteers, and most of them have no sleeping problems. By studying them, researchers will be able to define normal sleeping behavior to compare with problem sleep.

The children stay at the sleep "camp" on the Stanford campus for six days. Machines which measure eye movements, muscle tone, respiration and brain patterns monitor the children during six 20 minute naps each day and their nighttime sleep.

When they are not sleeping the campers take tests involving word memory, listening skills and mathematics to determine their alertness.

The children also have a chance for recreation--they play board games, participate in a variety of athletics, play musical instruments or go bowling. However, they cannot swim because the electrodes they wear cannot get wet.

Mary Carskadon, research assistant supervising the laboratory, notes that eleven staff members, many of whom are Stanford undergraduates, provide an extremely high staff/camper ratio for the 24 participants. They try to make the children's experience as enjoyable as possible. When the staff learned one girl would have a birthday while at camp, they arranged a party complete with cake and presents.

The study will continue after camp ends. Children identified as "sleepy" will be tested in the Stanford Sleep Research Laboratory and children referred to the Stanford clinics for sleep problems and learning difficulties will also be studied.

STANFORD--Dr. Christina Harbury, assistant professor of medicine at Stanford University Medical Center, accepted a research grant from the Hemophilia Foundation of Southern California in a special event in the office of San Francisco Mayor George R. Moscone on Tuesday, August 10, 1976.

This was the second installment of a $15,500 grant for research on hemophilia, a hereditary disease in which one of the 10 proteins in blood plasma that cause coagulation is missing.

The initial portion of the grant was presented last year to the now late Dr. Judith Pool, who discovered a way to separate the clotting factor from blood in 1964, eliminating the need for massive doses of blood for hemophiliacs.

Before her death in 1975, Dr. Pool was investigating a clotting factor concentrate believed to offer hope for hemophiliacs who develop antibodies to treatment with the plasma protein.

Most hemophilia patients today can be treated successfully with infusions of the clotting protein known as antihemophilic globulin (AHG), also called Factor VIII. However, about 10 percent of these patients develop an antibody to the protein which greatly complicates their therapy.

Dr. Harbury is continuing Dr. Pool's work, studying the immunological characteristics of Factor VIII and of the antibody which might lead to an understanding of what is different about the 10 percent of hemophiliacs who develop the complication.

Dr. Harbury, a native of Sweden, received both her undergraduate and M.D. degrees at Stanford, and has been involved with the hematology work at Stanford since 1966. She is head of clinical and special coagulation laboratories.

STANFORD--Dr. John D. Earle has been appointed head of the radiation therapy division of the Mayo Clinic in Rochester, Minnesota, the Clinic recently announced.

Earle, 38, an assistant professor of radiology, has been associate director of Stanford's radiation therapy division since 1973.

He hopes to develop an active training program and a basic research program at the Clinic, while expanding the clinical research currently being done there in radiation therapy.

Earle has seen great advances in radiation therapy techniques and feels the gains of recent years in radiation therapy and chemotherapy need to be consolidated in order to provide the most effective treatment for various cancers.

Earle received his B.A. in biology from the University of Oregon and graduated from Stanford Medical School in 1964. He interned at the Graduate Hospital of the University of Pennsylvania and was a fellow in radiation therapy at Stanford for three years. After serving in the Navy, Earle returned to Stanford as assistant professor of radiology.

STANFORD--Dr. Herant A. Katchadourian has been promoted to professor of psychiatry and behavioral sciences. The appointment was announced by Clayton Rich, dean of the Stanford University Medical School.

Katchadourian, 43, will also become vice-provost and dean of undergraduate studies September 1.

He is originator of Stanford's most popular course--human sexuality--and is known to more than half the University's undergraduates and hundreds of alumni through his lectures and books on the subject. About 1,000 undergraduates enrolled in the human sexuality course during the last winter quarter.

Katchadourian came to Stanford in 1966 as assistant professor of psychiatry and coordinator of the psychiatry residency training program. He served as Stanford's first ombudsman and is a former University fellow. He has been associated with the human biology program since its inception in 1969 and intends to continue to teach as a dean.

Katchadourian was born in Iskenderun, Turkey of Armenian parents and was educated in Beirut, Lebanon. He received both his B.A. and M.D. degrees from the American University in Beirut. He interned in Beirut and did his residency training at the University of Rochester.

Author of "Human Sexuality: Sense and Nonsense" and coauthor of "Fundamentals of Human Sexuality," Katchadourian is coauthor of a forthcoming book-length study of a Lebanese-Armenian community.

FOR IMMEDIATE RELEASE

STANFORD –

A Stanford University Medical School life sciences technician who was permanently laid off last year has agreed to an out-of-court settlement award of $12,500 following a series of lengthy legal actions.

Under terms of the agreement, Roscoe (Rocky) McGill and United Stanford Employees (USE), which served as McGill's collective bargaining agent while he was an employee, agreed to drop all pending legal actions against the University, and waive all claims arising from his employment. Among the claims was one seeking back pay and damages of $700,000.

McGill, who is black, was hired in 1971. He was informed in January 1973 that he would be laid off in June of that year. The University said the layoff was necessary because his research unit was to withdraw from a project which McGill and another employee were working on. McGill's fellow employee, who is white, had also been notified of the pending layoff.

McGill filed charges with the Equal Employment Opportunity Commission (EEOC), alleging that the layoff was the result of racial discrimination.

Prior to the announced layoff, McGill was rehired elsewhere in the School of Medicine. Nevertheless, he continued to press his charges before the EEOC. The commission ruled that there was reasonable cause to believe that the University had violated provisions of the Civil Rights Act in denying McGill cross-training in other skills which would have prevented his dismissal.

While in his second position, McGill was suspended for disciplinary reasons and filed grievance against the University. His suspension was upheld by Arbitrator Louis Garcia, former commissioner of the Fair Employment Practices Commission, and now a judge in San Francisco municipal court.

But USE filed a petition in superior court to overturn Arbitrator Garcia's decision.

In December 1975, McGill filed suit in federal district court claiming "certain adverse actions," including his layoff, were the result of race discrimination by Stanford. In the suit he sought reinstatement to his former position, back pay, and damages amounting to $700,000.

In addition, McGill and USE had filed four grievances, which had already proceeded to arbitration and had gone through 14 days of hearings when the final settlement was reached.

According to University staff counsel Douglas Barton, the four grievances pending before the arbitrator were dismissed as part of the settlement with McGill and the union. Also dismissed were McGill's federal court suit and the union's superior court petition.

McGill has, in addition, withdrawn his EEOC charges, waived any other claim to reinstatement, and has released the University from any other claim he might subsequently raise concerning his Stanford employment.

Barton said the University decided to settle all claims for the payment of $12,500 even though "we certainly were confident the arbitrator would have sustained Stanford's position.

"However, Mr. McGill would still have had the right under federal law to pursue his claims in federal district court and have a complete rehearing of all issues relating to his allegations of race discrimination." Barton cited the extensive expenses and other hardships that continued litigation would have brought.

FOR IMMEDIATE RELEASE

Following is a joint statement by Stanford University and the United Stanford Employees bargaining team, issued Sept. 29, 1976:

In a bargaining session Wednesday afternoon, the union and University bargaining teams suryeyed outstanding issues and agreed to meet intensively in an effort to resolve the major remaining issues.

Additional bargaining sessions have been scheduled for Thursday and Friday, Sept. 30 and Oct. 1.

In order that the bargaining representatives of both sides will be able to devote their undivided attention to these and subsequent sessions, public comment on negotiations will be made only through joint statements until further notice.

FOR IMMEDIATE RELEASE

STANFORD –

Officials of United Stanford Employees failed to get authorization to call a strike against the University Tuesday, Sept. 28, as the ballots from union members were counted.

The final tally was 37 votes short of the necessary two-thirds needed for strike authorization, USE president Roger Hardy reported.

The 538-327 vote will send USE back to the bargaining table, Hardy said, indicating the union will possibly poll the membership again.

"Another strike vote will be determined totally by the progress of negotiations," he said.

"It's an overwhelming mandate to reject the University's latest proposal," he said. "The membership gave us a sense that our demands are pretty much rock-bottom line."

Union members meeting Tuesday noon reported a "disturbing" trend of harassment by some University supervisors, Hardy said.

"We will try to go through appropriate chanels to get relief for workers, but because USE has no access to any disciplinary procedures (under an expired contract), the only way to combat harassing tactics may be job action."

Negotiating teams for both sides are scheduled to meet again Wednesday, Sept. 29.

* * *

Negotiators for the University and USE met in three bargaining sessions last week and reached agreement on some noneconomic issues, even while union officials waited the return of USE members' strike ballots.

The sessions were quite productive, according to Douglas H. Barton, counsel for employee relations and the University's chief negotiator. At Friday's session, the University team presented proposals about temporary promotions to supervisory positions, benefits for employees on temporary layoff, and disciplinary procedures.

Although both sides are still far apart on wages and benefits, substantial portions of the contract have been agreed upon at the bargaining table since negotiations began in July. The contract, which covers 1,350 technical, maintenance, and service employees at Stanford, expired Sept. 15 after a two-week extension.

Issues yet to be resolved include the question of union security, job classifications, certain provisions concerning training and job posting, and the major issue of wages and benefits.

The union earlier rejected the University's proposed wage and benefit package which would provide for about a 22% increase in compensation over three years.

Under the University's proposal, bargaining unit employees would receive first-year increases of 7.5%, second-year increases of 5.5% plus additional increases for certain job classifications costing an additional 1% of the wage base, and third-year increases of 5% plus a cost-of-living escalator costing up to an additional 2.2%.

Substantially improved retirement benefits for longer-service employees in the Staff Pension Plan were included in the University's economic package.

USE has proposed a pay package that calls for increases in the first year costing 14.5% of the wage base, a second-year gain of 8%, and third-year increases based on a quarterly cost-of-living escalator. USE's economic demands include proposals for either a dental plan for employees and dependents, or University payment of the full cost of existing medical coverage, or a substantial increase in pension benefits.

STANFORD--Six weekly lectures on important areas of research in medicine will be presented by professors from the Stanford School of Medicine beginning October 12.

Topics will range from cardiac transplantation to diabetes mellitus and the protection of human subjects in research.

The Stanford Alumni Association's fall quarter course will consist of six evening lectures on campus, October 12 through November 16. The series is open to the public, and preregistration is required through the Association, located at Bowman Alumni House on the Stanford campus.

The first lecture will be October 12, presented by Dr. William Robinson, professor of medicine (infectious diseases), who will discuss "Protection of Human Subjects in Research at Stanford." Dr. Robinson is chairman of the medical subpanel of the Stanford committee on the use of human subjects in research. His scientific work has been concerned with the structure and replication of several viruses.

On October 19 Dr. Jerrold Olefsky, assistant professor of medicine, will discuss "Diabetes Mellitus--Insulin Deficiency or Insulin Resistance?" Dr. Olefsky is investigating reasons for insulin resistance in some diabetics who have abnormally high blood sugar levels despite high levels of insulin in their blood.

On October 26 Dr. Gerald Reaven, professor of medicine, will speak on "The Effect of Diet on Blood Lipids--and Why Do We Care?" Dr. Reaven heads the endocrinology and metabolism research team at Stanford. His research is in hyperlipidemia, abnormal carbohydrate metabolism and atherosclerosis.

On November 3 Dr. Peter Greenberg, assistant professor of medicine (hematology) will discuss "Factors Involved in the Progression of Leukemia." Dr. Greenberg's research has focused on the mechanisms involved in the clinical evolution of the disease. He is studying factors such as the alteration of bone marrow cell function.

On November 9 Dr. Thomas Merigan, professor of medicine and head of the division of infectious diseases, will speak on "Vaccines, Antibiotics, and Now, Antivirals?" Dr. Merigan has received international recognition for his work with interferon, and antiviral substance occuring in the human body. He is part of the team that recently reported successful treatment of chronic hepatitis B virus infection with interferon. In 1973 he and his colleagues reported they had successfully used interferon to prevent common cold infections in human volunteers.

On November 16 Dr. Edward Stinson, associate professor of cardiovascular surgery, will discuss "Cardiac Transplantation at Stanford." Dr. Stinson has been one of the mainstays of the heart transplantation program since its inception at Stanford. Early in the program he identified a comprehensive plan for understanding and dealing with cardiac rejection, and he continues to contribute new techniques for diagnosis of rejection, as well as investigating a wide range of cardiological disorders.

STANFORD--A Stanford University Nobel Laureate Wednesday (Sept. 22) called for legislation committing the federal government to invest a fixed percentage of the dollars spent for health in basic research.

Spending, for example, 5 percent of the health industry dollar for basic research to make medicine more technologically reliable would seem a prudent and conservative investment, said Arthur Kornberg, professor of biochemistry.

"An investment of this size would call for immediate expansion of biomedical training and research rather than the retrenchment which has taken place and is being planned in the future," he said.

Kornberg made his remarks at a meeting on the future of academic pathology at College Park, Maryland.

The retrenchment began during the Johnson administration, he said. "One of the Johnson legacies that Richard Nixon eagerly accepted was this impatience with basic research. His administration called for crusades to vanquish cancer and heart disease without regard for the fact that we lacked the weapons to conduct such major wars at that time."

"Despite all that the history of medical science has taught us," said Kornberg, "there is an irresistible urge to gamble on a quick payoff."

The biochemist explained that it makes little sense to legislators to fund something as esoteric as the life cycle of a bacterial virus when cancer ravages their relatives and constituents.

Yet he added, "We can show that the pathway to practical benefits started from fundamental science and it was circuitous and took many years to traverse.

"We can point out the key discoveries which made X rays, penicillin and polio vaccine possible were not related to research on disease.

"These medical miracles came from the curiosity of physicists, bacteriologists, biochemists and cell biologists about basic scientific questions unrelated to medicine."

Once the insights and techniques were discovered, Kornberg said, the applications to medicine were rapid and dramatic.

"Conversely, crash and costly programs directed to the curing of diseases have invariably failed when the basic knowledge needed for application was lacking," he added.

Kornberg said he was not optimistic about the efforts by scientists to assure sustained support to advance basic biology and its applications to clinical medicine.

He said few scientists wish to engage in the political process needed for a federal long-term commitment for biomedical research, including support for basic science. ### Mailed Tuesday, Sept. 21, 1976

STANFORD--Participants in a new diet and weight control program at Stanford Medical Center are learning to be their own behavioral therapists.

The classes, offered by the Stanford Heart Disease Prevention Program and open to the public, focus on the behavior modification approach to changing eating habits.

They will serve as a model for a cooperative program between Stanford and the National Council of YMCAs. The aim is to change dietary quality and reduce weight in order to improve cardiovascular health, according to Dr. John Farquhar, director of the Heart Disease Prevention Program, and Dr. Gary A. Fry, director of the YMCArdiac Therapy program.

The emphasis is on helping participants recognize their own eating problems and how to solve them, rather than rely on fad diets or a list of "how tos," according to Drs. Joyce Nash and Linda Ormiston who coordinate the classes.

The program was inaugurated last Spring, and a new series of 12 weekly evening classes will be forming in October.

According to Dr. Nash, "We help the individual to identify his eating-related behavior patterns, and then learn techniques for changing these patterns." Problem areas might be with specific food groups, time devoted to eating, emotions, buying food, or could be entertaining or eating out problems. Not everybody in the class works on the same problems.

"The exciting thing is developing a person's self-control. The individual becomes his own therapist, not responding to someone saying 'you must do this,'" says Nash.

Participants are also urged to increase their level of activity, for both fitness as well as increase metabolic rate to take off pounds more rapidly. Each wears a pedometer to help increase consciousness of the amount of exercise.

"We encourage natural ways to promote activity, like walking more," says Nash. The pedometer also acts as a motivating device, she says, so the person can do more exercise if he feels he needs to.

Besides help with attitudes and behavior, participants hear from a nutritionist, although they are not given a specific diet plan. "Persons need to live in their particular life style," says Nash, "They need to learn to make reasoned choices."

One class member lost 22 pounds in 16 weeks, but quick weight loss is not the objective of the program, say the directors.

Weight loss of one to two pounds per week is a reasonable goal, says Nash, but the emphasis should be on gaining control of eating habits, thoughts and feelings so that maintenance of weight loss is permanent.

Because participants learn to measure their success in terms of behavior change and not weight loss, some choose to not know the results of weekly weigh-ins. They get on the scale backwards.

Participants may bring to classes a spouse, relative or other person who could influence their food habits. Although a fee is charged for the class, there is no charge for the guest.

One class member reports a particular help in having her husband attend and understand her problems. "When we had guests who brought a gift like candy, he would quietly put it away and remove the temptation," she said.

Others note that the intensive classes and "homework" forced them to think more about what they were eating. "It's something you must deal with 24 hours a day," said one woman. "Keeping track of your behavior helps you become prepared to deal with all the problem situations you encounter."

One woman liked being in control of her own diet plan: "For the first time in my life, I don't feel guilty when I eat something."

Based on these classes, personnel from the YMCA will be trained in conducting similar programs for the future.

Long-range plans call for developing slide and tape programs, with group discussion led by paraprofessionals. Such programs would be available on a wide basis to individuals or small community groups.

STANFORD--A distinguished cardiovascular surgeon and a noted pediatrician have been named as the first occupants of two new endowed chairs at Stanford University School of Medicine.

They are Dr. Norman E. Shumway, the Frances and Charles Field Professor of Cardiovascular Surgery, and Dr. Ruth T. Gross, the Katherine Dexter and Stanley McCormick Professor.

Dr. Gross is the first woman at Stanford to be named to an endowed professorship.

Announcement of the chairs was made Wednesday (Sept. 15) by Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine.

Dr. Shumway, chairman of the department of cardiovascular surgery, is known for his pioneering work in the field of open-heart surgery, correction of congenital heart defects in children, and heart transplantation. A graduate of Vanderbilt University and the University of Minnesota, Shumway is recipient of numerous awards including the Lerische Prize of the International Society of Surgery, and the Texas Heart Institute Medal.

Dr. Gross, director of the Division of Ambulatory Pediatrics and chief of pediatric clinics, has contributed new approaches to comprehensive health education and care for children, and improvement of pediatric training programs. A graduate of Barnard College and the Columbia University College of Physicians and Surgeons, Dr. Gross has held academic appointments at Radcliffe Infirmary, Oxford, Albert Einstein College of Medicine and the University of California. In addition, she has served as chief of pediatrics at Mount Zion Hospital and Medical Center in San Francisco, and as an associate dean for student affairs at Stanford. Last summer, Dr. Gross received the Henry J. Kaiser Award for outstanding contributions to medical education.

Funds for the Field endowed professorship were contributed by Mr. and Mrs. Charles Field of San Francisco, who have also endowed a professorship in history.

Mr. and Mrs. Field are both members of families that came to California during the nineteenth century. Frances Field's family held interests in San Francisco banking and West Coast lumbering concerns; members of Charles Field's family were in mercantile and financial firms in San Francisco and Los Angeles. Field, who holds a Stanford history degree, was until recently associated with an investment management firm in San Francisco.

The Fields have long been active in Stanford affairs. They are members of the Associates of the Stanford University Libraries and the committee for art, and are supporters of the Buck Club and Inner Quad. Mr. and Mrs. Field have stipulated that after Dr. Shumway retires, the chair will be known as the Norman E. Shumway Professorship.

The McCormick professorship in the School of Medicine will be funded by a portion of a $5 million unrestricted bequest made to Stanford in 1969 by Mrs. Katherine McCormick who spent her long life vigorously championing women's rights and welfare. The gift was made in memory of her late husband, Stanley McCormick whose father's company, later became the International Harvester Company.

Mrs. McCormick died in 1967 at the age of 92. She was a co-founder of the League of Women Voters. In bequeathing the money to Stanford, Mrs. McCormick had expressed the hope that funds could be used "for the encouragement and assistance of women in pursuing the study of medicine, in teaching medicine, and in engaging in medical research."

STANFORD--Dr. LeRoy Heinrichs has been appointed professor and chairman of the Department of Gynecology and Obstetrics at Stanford University School of Medicine.

Heinrichs' appointment was announced by Dr. Clayton Rich, vice president for medical affairs and dean of Stanford Medical School.

A nationally recognized scientist and clinician, Heinrichs has been the leader of a research group working on the biochemistry and physiology of sex hormones. His current studies are concerned with how prenatal hormones imprint in the fetus the regulation of metabolism in adulthood.

Heinrichs, 44, has served as professor of gynecology and obstetrics at the University of Washington School of Medicine. Earlier, he served as a clinical instructor in the Department of Obstetrics and Gynecology at the University of Oregon Medical School and recently was a visiting fellow at Battelle Memorial Institute's Research Center in Seattle, Washington.

A member of numerous professional organizations, Heinrichs is also acting editor of Gynecologic Investigation, and international journal of the science of reproduction.

Heinrichs earned a bachelor of science degree from Southwestern State College in Weatherford, Oklahoma, his M.D. from the University of Oklahoma and his Ph.D. in biochemistry from the University of Oregon.

His training in gynecology and obstetrics was at Harper Hospital of Wayne State University, Detroit, Michigan. He succeeds Dr. Charles E. McLennan, who served as chairman of the Department of Gynecology at Obstetrics for 26 years prior to retiring in 1972. ###

STANFORD--Family Focus, a training program for patients with physical handicaps, has been renewed for two years under a $128,000 grant from the U.S. Public Health Service's Bureau of Allied Health Manpower Education.

The program, which is coordinated by the Division of Physical Therapy at Stanford School of Medicine, includes counseling and assistance by physical therapists to help patients and their families manage their disability once they are discharged from the hospital. The grant covers training of masters degree students in physical therapy working in the Family Focus project.

As part of the project, families are housed temporarily in a specially-designed, modular home located behind Stanford Hospital's Hoover Pavilion. Persons in the program are then shown how to deal with the daily health care needs of the patients, and how to handle any unusual circumstances that might arise at home.

STANFORD--"The Heart: Its Life and Yours" will be the subject of a symposium to be held at Stanford October 1-2, conducted by medical specialists from the Stanford School of Medicine.

The aim of the meetings, which are open to both medical professionals and the public, is to discuss how the heart functions physiologically, how symptoms of heart disease are diagnosed and what sorts of treatment are possible.

The event is part of the continuing education program sponsored by the Stanford Alumni Association. Preregistration is required and forms are available from the Association at Bowman Alumni House on the Stanford campus.

The symposium will begin on Friday evening, October 1 with an introduction by Dr. Donald Harrison, holder of the William G. Irwin professorship and head of the division of cardiology at Stanford. In addition, Dr. William Barry, assistant professor of medicine, will speak on the anatomy and physiology of the heart.

On Saturday, October 2 topics will include the early diagnosis and electrophysiologic testing for heart disease, by Dr. John Schroeder; the heart as a pump, by Dr. Edwin Alderman; special X ray studies, by Dr. Lewis Wexler; medical treatment of heart disease, by Dr. Roger Winkle; surgical treatment, by Dr. Eugene Dong; risk factors, by Dr. John Farquhar; and rehabilitation of the heart attack victim, by Dr. Robert DeBusk.

Heart disease prevention workshops are planned for the Saturday afternoon session, with participants able to choose sessions on stress management, weight control and diet change, ways to stop smoking, and on exercise.

STANFORD--Researchers at Stanford University Medical Center report they have successfully treated chronic hepatitis B virus infection with the antiviral substance, interferon.

The investigators tested the effectiveness of interferon in battling chronic hepatitis B virus which affects as many as one million people in the United States today. Their findings are reported in the current issue of The New England Journal of Medicine.

They emphasize their findings are preliminary and further testing is required before interferon will be considered for general use. Additional patients infected with chronic hepatitis B virus are currently being sought and evaluated for possible interferon treatment.

Hepatitis viruses cause inflammation of the liver. There are two major viruses which cause hepatitis--infectious hepatitis A virus which is associated with epidemic jaundice and hepatitis B virus which is associated with blood transfusions and unsterile needles used in injections.

About 10 percent of those who develop acute hepatitis B continue to carry the virus in their liver and blood indefinitely. Some of these chronically infected people feel fine and do not even know they have the disease, but they can transmit it to others who may or may not develop symptoms says Dr. Harry B. Greenberg, a member of the research team.

Doctors who participated in the study are: Greenberg, a gastroenterology fellow; Richard B. Pollard and Larry I. Lutwick infectious diseases fellows; Peter B. Gregory, assistant professor of medicine (gastroenterology); William S. Robinson, professor of medicine (infectious diseases); and Thomas C. Merigan, professor of medicine and head of infectious diseases.

Four patients with different degrees of chronic hepatitis B virus infection were selected by the team for treatment with interferon, a protein produced by the body's defense systems to limit the spread of viral infection.

Prior to treatment the blood of each patient carried Dane particles which appear to be the complete hepatitis B virus, according to Robinson, who developed a test to measure their presence in blood. Patients were given interferon either for one week or for a month or more.

-more-

Interferon significantly reduced or eradicated evidence of the Dane particles in all patients. However, once interferon therapy was concluded, the short-term therapy group which had shown a decrease in Dane particles during treatment demonstrated an increase to previous levels. The extended therapy group's Dane particle decrease "seems to be long lasting" say the investigators.

"Interferon appears to be exerting a suppressive effect on the production of Dane particles," says the report. But it cautions, "Whether these effects will be of therapeutic value in limiting carrier infectivity or eradicating chronic infection remains to be shown." Post treatment serum from patients with no detectable Dane particles will be tested to determine if it will still cause hepatitis.

The National Institutes of Allergy and Infectious Diseases (NIAID) has supported a major portion of Stanford's antiviral research. In commenting on the hepatitis project, the Institute's director, Richard M. Krause, said, "These studies are indeed encouraging and it is expected that if this therapy does prove to have long-term effectiveness, it will be a major step in the advancement of antiviral agents. This is an area of long-standing interest in the Institute and we hope these studies will provide the impetus for further advancement."

Interferon, which was supplied for the study by the NIAID, is in limited supply and is very expensive. The only present source of interferon is human white blood cells, although drug companies are beginning to produce the substance in human cells grown in the laboratory. This could increase the supply and decrease the cost of interferon.

The researchers feel their findings could set the stage for treatment of other chronic viral infections. Merigan, who has shown interferon's effectiveness against the common cold, hopes the substance will block viruses with the same efficiency that antibiotics destroy bacteria.

EDITORS: Following is a commentary by Dr. Rodney R. Beard, professor and head of the Division of Preventive Medicine at the Stanford University School of Medicine. In his specialty he has used influenza vaccines for 30 years. His article explains the reasons for the swine flu vaccination program, and why he believes it is important for each individual to take part.

FOR IMMEDIATE RELEASE

STANFORD –

Many people are in doubt about the value of the swine-flu vaccine.

I believe most people should take the vaccine. At the price of a little time and possibly a mild reaction for a few hours, one can get at least some protection from what could be a devastating illness. It could contribute to the prevention of a worldwide pandemic.

Influenza vaccines became available for widespread use about 30 years ago. Their effectiveness was uncertain and sore arms and illness were frequent. Scientists learned there were several varieties or strains of influenza virus. A sufficient injection of killed virus of a given strain would give rather good protection against infection by that same strain. However, one could not predict which strain might be prevalent in the next flu season. Also, the protective dose was likely to cause quite a few unpleasant reactions—sore arms and fever. None of these reactions was severe, however. No deaths directly caused by vaccination have been recorded.

As time passed, more was learned about influenza viruses. Some degree of skill was attained in predicting which ones would occur in the U.S. and some other areas. At the same time, new knowledge and skills made possible purified vaccines which caused very few reactions, all mild.

Influenza epidemics in the U.S. have generally been imported. The virus strain which caused each U.S. epidemic first caused an epidemic in another part of the world. Public health workers began to dream of the day when a worldwide network of observation posts would promptly identify the virus strain of a new outbreak. A vaccine from the same strain, or one closely similar, would then be produced and administered in areas as yet unaffected, thereby putting up a barrier against further spread of the virus.

An opportunity for this occurred with the Asian flu which hit the U.S. in 1957-58; the virus had been isolated in Japan and was brought to U.S. vaccine manufacturers months before the disease appeared in this country. For various reasons a vaccine was not produced and many preventable deaths occurred.

But the idea didn't die. When an epidemic started in Hong Kong in 1967, another effort was made: this time, 100,000 doses of vaccine were released in the U.S., but only two weeks before the outbreak hit us, and it didn't do much good. Another time we could probably be successful.

Early in 1976 there was a lot of respiratory disease among Army recruits at Fort Dix, N.J. However, as the weeks progressed the numbers swelled much more than usual. By the end of the month it was suspected that a flu epidemic was in progress. Throat washings s from hospital patients were shown to contain flu virus. Most were of a strain known as A/Victoria, which was widespread in New Jersey at that time. A few were of a different strain, later identified as A/Swine.

The swine flu virus has been especially interesting because virologist think it might have been the cause of the devastating 1918 pandemic. This idea is based on finding antibodies for the swine flu virus in many people born before 1918, but not in those born later (unless they had worked with pigs). The virus is widely distributed among pigs and is sometimes transmitted to man from them. But man-to-man transmission of the virus was unknown.

The unique feature of the Fort Dix outbreak was that swine flu virus was transferred from man to man. This was shown by isolation of the virus in five cases, by increases in swine flu antibodies in eight more, and by the finding of swine flu antibodies in the blood of over 500 young men who had neither worked with pigs nor lived through the 1918 epidemic.

With understandable enthusiasm, though questionable justification, reporters and others soon began to refer to "the killer virus." This epithet rests on the terrible history of the 1917-18 pandemic, which had caused more havoc in London than the Great Plague.

(more)

In the U.S. those years show great spikes on the graph of annual death rates. It attacked not only the young and the old, but also many vigorous people in early maturity and middle life. It was not unusual for a previously healthy person to die within 24 hours from the onset of the disease. Although we now have antibiotics which can cure the bacterial pneumonias that killed many patients in the 1918 epidemic, there were cases in which there was not enough time for such treatment. If this were indeed the virus present at Ford Dix, the outlook would have been for disaster.

The swine flu disease observed at Fort Dix was not unusually severe. One person died, but it was after he disregarded advice to stay at home and went on a forced march.

The reasons for serious concern were that a virus strain which had not previously passed from man to man was now doing so; that it was a strain which had possibly been derived from that responsible for a devastating pandemic; that on the basis of long experience we are about due to have another pandemic. (Historically, pandemics have been observed at about ten-year intervals, and the last was in 1967-68).

Public health officials faced a difficult choice: Viewed in one way, it could be said that there was no proof that the Fort Dix observations were not just a fluke; perhaps similar limited epidemics of swine flu had occurred but had not been recognized; no one could be certain that a swine-flu vaccine would work; some people inevitably would blame the vaccine, rightly or wrongly, for subsequent illnesses; it would be a costly experiment to put up an imperfect vaccine against the risk of a presumed epidemic.

Viewed another way, it was the first good opportunity to nip the bud of a pandemic; vaccines had been effective on many occasions; the newer purified vaccines caused few reactions; the potential for a devastating pandemic could be great; there was adequate time to produce enough vaccine before the next flu season if the decision were made without delay.

In the light of all this, the Public Health Service officials, with the agreement of their expert advisers, decided they could not conscientiously withhold from the public this opportunity for health protection. The President and Congress agreed with them that the prudent course would be to embark on a national vaccination program. The vaccine was produced and the injections are under way.

Now questions are raised about safety, effectiveness of the vaccine, and the need for the program.

As to safety, few reporters take note of the tens of thousands already injected with minimal complaints of soreness or illness. Much emphasis has been placed on the deaths of some chronically sick people soon after they received the vaccine. It must be remembered that sick, elderly people are likely to die anyway. We should expect about one death among 10,000 old people each day. In no instance reported to date (Oct. 22) has there been cause-effect relationship between the vaccination and death.

In one episode, three old people with heart and lung disease who received the vaccine at one station died within a day. This was more than was expected, and an extensive investigation is under way. So far, no specific cause for their deaths on this particular day has been found.

There is no significant reason to doubt that any healthy adult can take the vaccine safely, with very little risk of even a sore arm as a result. Any sick person, especially anyone with chronic illness, should take the advice of his personal physician. For many such people, the vaccination could be life-saving, but for others it could be harmful.

As to efficacy of the vaccine, the best that can be done to test it is to see if it causes humans to form antibodies, and this it does. It is fully potent in evoking antibodies against one factor of the virus called the hemagglutinin factor. It is ineffective in evoking antibodies against a second factor, the neuraminidase factor. There is some desagreement among experts as to the importance of the second antibody; a majority believe the hemagglutinin antibody most important for the prevention of infection.

As to the need for the program, it is said by some that there has been no further outbreak of swine influenza in this country or elsewhere in the world.

The answer is that all pandemics must start somewhere, and there is no reason one shouldn't begin in the U.S. To wait for other appearances of the virus would throw away the chance of keeping the outbreak under control.

STANFORD--An automated system developed at Stanford for mass screening of newborn babies for deafness is being tested at fifteen hospitals throughout the country.

The device, called the crib-o-gram, was developed by Dr. F. Blair Simmons, head of the division of otolaryngology and Frederica Jones, R.N., at Stanford University School of Medicine.

Hospitals in Massachusetts, Illinois, New York, Colorado, Florida, Texas, Virginia, Iowa, Nova Scotia and California are participating in the crib-o-gram study. The data they accumulate for two years through June 1977 will be analyzed by Simmons and his team to determine crib-o-gram's reliability.

The device monitors infant movement before, during and after a test sound is emitted from a microphone in the ceiling of the nursery. It is so sensitive it can detect breathing, heart beats or hiccups. The infant's activity is recorded on a paper tape during the night which is scored the following day.

The device has been used in the Stanford nurseries for six years. In that time more than 10,000 babies have been tested. The 1,000 who failed the test at birth were again screened at six months. Of those, 23 were confirmed to have hearing losses. The incidence of hearing loss in babies in the intensive care nursery is significantly higher than for infants in the well baby nurseries.

"Hearing rehabilitation is most successful if it is begun around six months of age," explains Simmons. "Yet very few children with hearing defects are discovered before they are one. In fact, most problems are not detected until children are two or three, when their language development falters. Testing hearing at birth or soon after can improve the chances of normal speech and language development," he notes.

If hearing loss is detected early, children can be taught to use whatever hearing they have as well as lip reading so they can attend regular classes at public schools. Their improved communications skills will help them lead more normal lives, says Jones.

The incidence of deafness in newborns is one or two per thousand, Simmons says. Since it is a relatively small ratio, nursery staff and pediatricians do not always feel it is worth their time to screen every infant individually, he says.

"With the crib-o-gram, little extra time or effort is involved," explains Simmons. "Everything can be mechanized, with an average cost of less than one dollar per child."

The heart of the automatic system is an inexpensive motion detector called a transducer. It is commonly used by burglar alarm companies to detect floor movement caused by walking. When mounted on the crib frame, it detects the stress caused by movement in the crib.

The data from participating hospitals will help determine the device's effectiveness. It has already demonstrated it can detect hearing defects in newborns, and at present appears to be the most effective mass screening technique available for infants.

STANFORD--A Stanford University surgeon Tuesday accused the American Association of Blood Banks (AABB) of making "misleading and partly deceptive statements" in claiming an impending blood supply crisis.

Dr. J. Garrott Allen said that when the American National Red Cross withdrew from the AABB's national blood clearinghouse last week, the trade association issued a statement predicting that blood shortages will develop and the cost of donated blood will rise.

"This claim is unwarranted," said Allen. "Locally an ample supply is available from the Central California Red Cross Blood Center in San Jose. The situation is the same elsewhere."

He said the American Blood Commission surveyed 23 blood banks nationwide. Twenty of the 23 said the blood supply was equal to or more than last year's. Most blood banks in the survey dispute the alleged crisis.

Allen, a noted researcher in blood coagulation and serum hepatitis, has been a long-time critic of blood banking practices. He has campaigned for reform and blood labeling laws to reduce the incidence of hepatitis attributed to blood from paid donors.

"It is important that donors not be misled," Allen stressed. He urged that they continue to give blood to the Red Cross. He also suggested that civic or employee groups with current commitments to AABB-affiliated blood banks reassess their relationships.

The AABB represents an important segment of the private sector in blood banking, said Allen. "It should be encouraged to continue but under conditions in which the patient's interest comes first."

"Blood banking as now represented by the AABB is big business," said Allen. "It is especially profitable under the AABB clearinghouse arrangement."

The clearinghouse is a system operated by the AABB representing some 2,000 non-profit and a small number of commercial blood banks. Under the program, blood donations can be credited to individuals in any area. The credits are computed and balanced among participating blood banks, and units of blood that are owed are then delivered.

Allen said the Red Cross withdrew from the clearinghouse because of objections to commercialism and AABB's use of a non-replacement fee. The non-replacement fee forces patients unable to replace blood to pay a penalty.

-more-

As a result, Allen said, the actual charge to patients for unreplaced blood, from such banks as Irwin Memorial or Peninsula, is $15 higher than when it is obtained from the Red Cross. The Red Cross charges only a processing fee and it is covered by insurance. The blood itself is free.

"Volunteer donors give blood to the Red Cross freely," said Allen. "It must go to patients who need it free of charge. "But the Red Cross discovered that when its blood went through the AABB clearinghouse, it was often sold, making a profit for AABB affiliates and betraying the donors."

Allen said the AABB recently sent a memorandum to its affiliates which has confused the public, patients and physicians.

The memo advised affiliates to alert hospitals and laboratories to discourage acceptance of blood from the Red Cross unless it was shipped through the clearinghouse which charges a fee.

The AABB memo also urged its blood bankers to tell patients that the Red Cross will no longer transfer blood credits on behalf of specific patients.

"This is true," said Allen, "only as it affects the clearinghouse. "But the Red Cross has informed me that it will deliver blood directly to any hospital to meet the needs of its patients."

Allen said the Red Cross will deliver blood to a hospital even if the patient has never participated in a Red Cross blood program. "This is one of the advantages of the Red Cross community, non-specified donor approach," he said.

Allen warned, "Any shortages of blood in the future could be created by hospitals willing to follow the advice of the AABB memorandum."

The surgeon said the AABB was attempting to interfere with blood collection functions of the Red Cross and other non-AABB blood banks.

He quoted the AABB memorandum which suggested: "You (blood bankers) may wish to...collect blood in Red Cross areas for individuals or groups who would like to establish credit in areas served by clearinghouse participants."

"This sounds as though the AABB wants its affiliates to send their bloodmobiles into Red Cross territory to bleed it dry." said Allen.

Allen said the AABB also advised its members to highlight the importance of the clearinghouse "in your area." It provided, he said, a sample news release with blank spaces for the name of the blood bank and its director to send to the local newspapers.

This was the story published widely in Bay area newspapers October 19.

Allen said such tactics do not serve the national interest nor that of the AABB. He said he had transmitted the material to the Department of Health, Education and Welfare, and to the state department of consumer affairs requesting an investigation.

It is the responsibility of the federal and state governments to determine whether such practices by a "non-profit" organization are proper, he said.

The AABB, Allen said, has consistently opposed other blood banking groups, including the Red Cross, which have formed a national commission for the private sector, the American Blood Commission.

"AABB is opposed because its affiliates would be required to make their financial records available for public inspection," said Allen. "For whatever reasons, the AABB wants to avoid this practice which is acceptable to the Red Cross and others."

STANFORD--It is painful for a child, or even an adult, to be physically different. Whether you are the tallest or shortest, the fattest or skinniest, others will have some derisive comment to make.

Like other physical characteristics, height is primarily a product of heredity. If you are short, your ancestors were probably short too. Occasionally a chronic disease can be responsible for decreased growth. Or sometimes people are small because they lack growth hormone. Doctors can supply that hormone to children who are deficient to help them reach a more normal height.

Dr. Raymond Hintz, Stanford assistant professor of pediatrics and a specialist in endocrinology, has been involved in growth hormone research and has used it to treat patients for a number of years. He was recently awarded a supply of growth hormone from the National Pituitary Agency for a Stanford-Yale study involving 50 children.

Growth hormone will not make every short person tall. Hintz cautions, "At our present state of knowledge, there is no hormone which is going to make someone bigger than their own genes dictate."

But if tests prove that lack of growth hormone is the cause of shortness after ruling out disease or heredity, treatment with the hormone can begin.

In most cases growth will follow, although not everyone will respond. Some children will begin to grow after the dosage is increased, while about 10 percent develop antibodies and no longer react to treatment. According to Hintz, at least 8 out of 10 diagnosed cases will respond successfully to the hormone.

Unfortunately, because the supply of this hormone is limited--it is strictly regulated and available only from the National Pituitary Agency (NPA)--it is only given until a patient reaches a height of five feet. Until there is a greater supply of the hormone, that is all the NPA will provide.

Growth hormone is extracted from the pituitary gland and acts primarily on bone, cartilage and muscle although it also affects other organs. To treat one child for one year, fifty pituitaries from donor-cadavers are needed, with average treatment lasting 5-10 years, says Hintz.

Only about half the needed supply of pituitaries are available in the U.S. today. However, they are not as scarce in other parts of the world where regulations concerning donor organs are less stringent. Growth hormone is an unregulated, prescription item in these places.

-more-

The hormone may soon be marketed commercially in this country, although supplies will still be limited and lengthy therapy will be expensive.

Only three percent of the population can be considered abnormally small, Hintz explains. About one percent are short due to growth hormone deficiency. Of the patients seen in Stanford's pediatric endocrinology clinic, 10 percent have some sort of illness which causes their shortness; the other 89 percent are short for no apparent reason other than heredity.

When a child comes to the clinic, the doctors first determine that he is free from disease. If this is ruled out, a history is taken and heights of all family members including parents, grandparents, aunts and uncles are recorded. Past growth records are also examined. "If a child has been growing at a certain rate and then stops or slows dramatically," says Hintz, "there is more concern than if he has always had a slow growth rate."

Hintz urges that treatment begin early. "You're more receptive to the hormone at a young age," he explains. "The chances of response begin to diminish after age ten. One of the problems we face is getting children who can benefit most from this therapy diagnosed early enough."

According to Hintz, once a child has started growth hormone therapy, two psychological problems are common. First is the so-called King Kong complex in which a child who has always been small begins to grow and becomes very aggressive. The second involves the child's inability to change his body image--he sees himself as a small, sweet child. When he becomes the same size as his friends, he loses his uniqueness.

Parents most often suffer from inflated expectations and hope the first injection of the hormone will make their child normal size. Although there is an initial growth spurt, it usually takes months to approach normal, says Hintz. It can even take years if therapy is begun late.

Hintz believes that understanding how growth hormone works may help to improve the therapy for its deficiency. An intermediary called somatomedin is stimulated by growth hormone. It is this intermediary which actually influences bone and cartilage to grow.

"We are studying the interaction of somatomedin with tissues and cells to learn why they grow. The intermediary is a smaller molecule than growth hormone and may be easier to synthesize once we know its structure," Hintz says.

Until a synthetic hormone is developed, supplies will remain limited. But as Hintz says, "We can now take a 15-year-old who looks six and make him look at least 12 by giving him growth hormone." While that 15-year-old may still want to be as tall as a basketball player, at least he's closer to normal height.

(ADVANCE) FOR A.M. RELEASE MONDAY, OCTOBER 25, 1976

STANFORD--Behavioral scientists at Stanford University School of Medicine have come upon a chance finding which shows that chimpanzees may predict earthquakes.

The research is carried out at the Stanford Outdoor Primate Facility located near Jasper Ridge Biological Preserve. The facility is adjacent to the San Andreas fault.

The scientists reported their finding Sunday, October 24, at a meeting sponsored by the U.S. Geological Survey in Menlo Park.

They are Dr. Helena C. Kraemer, associate professor of biostatistics in the Department of Psychiatry and Behavioral Sciences; Bruce Smith, a geophysicist with the Geological Survey; and Dr. Seymour Levine, professor of psychiatry and director of the primate facility.

According to Dr. Kraemer, interest in the project was triggered by recent Chinese reports of animal behavior changes preceding a major earthquake by as much as two months.

"While our evidence is not yet sufficient to conclude that animal behavior will predict earthquakes," she said, "it suggests a model for researching the question."

Popular reports of unusual behavior prior to an earthquake have been numerous, Dr. Kraemer noted. But they have been accorded little credence because of their anectodal and retrospective nature.

"Animal behaviors can be monitored and reliably measured," the researchers said. "We believe we have the first scientific evidence there are behavior changes that precede earthquakes."

Dr. Kraemer said animal studies would be particularly valuable for short-term and location forecasting. "But to prove it conclusively, we will have to predict the next earthquake," she added.

The primate facility is a unique research station housing chimpanzees born and raised in the wild. Opened in 1974, the center has been used by researchers and students to observe social behavior and hormonal changes among chimpanzees in a natural setting.

In locating the facility near the fault, Dr. Kraemer commented, Stanford officials had inadvertedly built an ideal model for studying the relationship of animal behaviors to earthquakes.

She explained that prior to a single swarm of minor earthquakes last June, observers at the facility had recorded "intriguing behavioral changes" among the chimpanzees.

"The animals were more restless than usual, she said. "They spent more time on the ground than high on their climbing structures and nesting areas. Their behavior change was so significant it seems unlikely it was due to chance."

-more-

222--Outdoor Primate Facility

Dr. Kraemer emphasized that at the time the animal behaviors were recorded, the observers were doing unrelated research. And they were unaware that any tremors had occurred.

Acting on a suggestion by Geophysicist Bruce Smith of the U.S. Geological Survey, Drs. Kreamer and Levine analyzed the course of chimpanzee behavior before and after 25 minor earthquakes had occurred in the vicinity between June 19 and 24.

The Stanford researchers found that the animal behaviors changed on the day prior to two of the largest earthquakes in this period. One took place June 19 and registered 3.1 on the Richter scale. The other earthquake occurred June 24 and measured 2.0.

In each instance, the signs of restlessness and change in location by the chimpanzees had occurred the day before, said Dr. Kraemer. Their behavioral change was less pronounced in the in-between period during which the area was experiencing tremors of lesser intensity.

The researchers said they are not yet ready to say that the behavioral changes were unequivocally due to the impending seismic activity alone. There may be other factors.

But they note the behavioral data were collected and stored in the computer before information about any earthquakes having occurred became available. Consequently, observer bias can play no role, they asserted.

"There were no unusual events which might have caused the chimpanzees to behave the way they did," said Dr. Kraemer. "And none of the observers took note of the earthquakes."

The researchers said it is unlikely that the Stanford facility would experience enough isolated earthquakes in a reasonable period of time to answer the questions raised.

"Multiple monitors," Dr. Kraemer suggested, "will be needed using perhaps less expensive animals, for example, poultry and cattle at ranches scattered along major faults.

"Trained observers or automated behavior monitors will be required, coupled with computerized systems for routine observation and data analysis."

In addition, the behaviors of each animal species will have to be studied, and decisions made as to the magnitude of change warranting an earthquake alert, she said.

Recently scientists have said that animal behavior studies will comprise the most significant effort in earthquake prediction in the next few years. Prof. Amos M. Nur, a Stanford geophysicist, was among those who had conferred with Chinese scientists after they had predicted a major earthquake in the city of Haicheng last year.

In an article in the Stanford Earth Scientist, Nur pointed out that a few days prior to the earthquake, a swarm of foreshocks occurred;"...at the same time, many reports came from a multitude of villagers concerning abnormal behavior in their livestock."

STANFORD--A graduate of Stanford Medical School's physician's assistant program and a current Stanford staff member have been appointed to the state's Physician's Assistants. Examining Committee of the Board of Medical Quality Assurance.

The appointments of Sergio Noriega, physician's assistant in Gonzales, California, and Stanford program staff member George Armstrong, were announced recently by Governor Edmund G. Brown, Jr. Terms are for four years.

The nine-member committee regulates physician's assistants practicing in California, their training programs, and approves the physicians who hire them.

The federal and state supported program is designed to aid overworked family doctors in the delivery of primary health care, particularly in underserved rural or ghetto areas.

The Stanford program is operated jointly with community colleges in Eureka, Redding, Modesto, Salinas and Bakersfield, and with Foothill College in Los Altos. The aim of the two-year program is to recruit and train people in areas where they plan to return to work in the health care field. The students come to Stanford for one quarter of clinical training in the Fall.

Sergio Noriega was a member of the first graduating class of physician's assistants from Stanford in 1973. He has worked since in the Salinas Valley community of Gonzales aiding general practitioners in the predominantly Spanish-speaking agricultural community.

George Armstrong has been field services coordinator at Stanford for the past two years, traveling thoughout the region to generate interest among communities and physicians.

The Stanford program has 70 assistants currently in training. There are 75 graduates now in practice, most with physicians in general practice in rural areas.

STANFORD--Dr. Seymour Levine will be the new director of the Stanford Outdoor Primate Facility.

He is professor of psychiatry and behavioral sciences. Levine's appointment, to be effective immediately, was announced Wednesday (Oct. 13) by Dr. Clayton Rich, vice-president for medical affairs and dean of the School of Medicine.

The primate facility is a research station housing chimpanzees born and raised in the wild. It is located on an isolated 24-acre tract adjacent to Jasper Ridge Biological Preserve and the Stanford Linear Accelerator.

Opened in 1974, the center allows researchers and students to observe social behavior and hormonal changes among chimpanzees in a natural setting.

Plans for the center were developed by Dr. David Hamburg, Reed-Hodgson professor of human biology, who served as its first director. Hamburg left Stanford this year to become president of the Institute of Medicine of the National Academy of Sciences in Washington, D.C.

Levine's research is in the areas of physiological and behavioral development, including stress, hormones and varieties of infantile experience, as they affect behavior.

Levine joined the Stanford faculty in 1962. He holds a Ph.D. from New York University, had been on the faculty of Ohio State University, and had spent two years as a fellow in neuroendocrinology at the Institute of Psychiatry at Maudsley Hospital in London, England.

He won a Hoffheimer Research Award in Psychiatry in 1961.

STANFORD--Full heart resuscitation equipment should be on hand in all dental offices using general anesthesia for minor oral surgery, a Stanford University anesthesiologist reported Monday, October 11.

Dr. Alexander Thurlow made this recommendation following a study of the high incidence of abnormal heart rhythms in 160 children, aged 7 to 14, who underwent dental surgery at the outpatient clinic of the Royal Dental Hospital in London, England.

Dr. Thurlow is attending physician at Stanford Medical Center and visiting assistant professor of anesthesia from St. George's Hospital, the University of London.

He presented his findings at the annual meeting of the American Society of Anesthesiologists in San Francisco.

According to Thurlow, recent studies have established that the incidence of cardiac arrhythmias occurring during general anesthesia for minor oral surgery is about 25 percent, or one in every four cases, a level he calls extremely frequent.

Cardiac arrhythmias in dental anesthesia, said the physician, are a worrisome problem. "They may account for several cases of unexplained collapse and death in the dental chair every year."

In light of such findings, Thurlow says essential drugs, electrocardiogram monitors, and portable cardiac defibrillators should be standard equipment in dental offices. Such equipment is not commonly available in British dental offices, he says.

In the U.S., such equipment is not required, although the American Society of Oral Surgeons has advocated that it be available in offices administering general anesthesia.

Portable resuscitation equipment, Thurlow says, is not prohibitively expensive, even though it may only be used rarely by an individual dentist.

"The chances of getting a patient out of ventricular fibrillation (cardiac arrest) are greatly reduced by an hour's wait for an ambulance and hospital equipment," he says.

Dr. Thurlow says British statistics count one cardiac arrest in 200,000 young, healthy patients undergoing oral surgery under general anesthesia. There were more than 40,000 cases of arrhythmias among the same group.

The physician's most recent study indicated that 37 children out of 160 (23 percent) developed a cardiac arrhythmia. However only 14 percent developed the disorder when anesthesia was begun intravenously and then continued by inhalation. Thirty-two percent arrhythmias were noted among those who received anesthesia only by inhalation.

Only 1 of 12 patients who received the initial intravenous injections developed serious disorders, compared to 12 out of 33 patients who received inhalation anesthesia.

The results confirm, he says, that intravenous induction with inhalation maintenance reduces both the incidence and severity of arrhythmias.

The physician also called for local anesthesia as the method of choice in patients for minor oral surgery. If inhalation anesthesia is indicated, he said, "patients should be routinely monitored and dental anesthesia should only be given where full cardiac resuscitation facilities are available." ###

EDITORS: Text of committees' responsibilities available on request.
FOR IMMEDIATE RELEASE
STANFORD –

A newly-formed panel, which includes a public representative and an outside expert in biosafety, will monitor and maintain safeguards for research on recombinant DNA at Stanford University.

William F. Massy, vice-provost for research, announced the formation of the group Tuesday, Oct. 5. The 12-member administrative panel on recombinant DNA molecules will be chaired by Prof. Allan M. Campbell of biological sciences.

Campbell, a 47-year-old microbiologist-geneticist, is not involved in recombinant DNA work.

A controversial issue in genetics, DNA recombination involves techniques which make it possible to select genes from one organism and transplant them into the chromosomes of another. Most researchers use bacteria as the recipient species to study the organization of complex chromosomes in ways that were not possible previously.

The research provides the potential for introducing genes into easy-to-grow bacterial cells, enabling construction of bacterial "factories" that will synthesize such medically needed substances as insulin, hormones or antibiotics. The method, its proponents suggest, also holds promise in agriculture, energy, and ecology.

From the beginning, however, it became clear to the scientists involved that these techniques could be used to produce novel gene combinations that may be biologically hazardous. They agreed in 1974 to a temporary halt of some experiments until guidelines could be worked out for safety.

After several public meetings, officials of the National Institutes of Health issued guidelines last summer. These detail the responsibilities of scientists and their institutions in doing the research.

The Stanford panel, Massy said, will review proposals and research activities involving DNA recombination. It will determine their acceptability with respect to procedures and facilities.

"The panel," Massy added, "will insure that those involved in such research comply with applicable policies, guidelines, and standards of good practice, thereby insuring safety of personnel and the general public."

The NIH guidelines ban certain experiments altogether, including those involving highly toxic substances. Experiments permitted under the rules are classified according to their potential hazards. The guidelines also define the safety precautions to be taken with each class of studies.

According to Massy, the panel will be responsible for reporting to University officers any potential or apparent violations of policies related to the research.

The Stanford panel met for the first time September 28. It voted unanimously to adopt the NIH guidelines to cover all recombinant DNA work on campus, he said.

The panel membership consists of six scientists of whom three are not involved in recombinant DNA research, one engineer knowledgeable in design and operation of containment facilities, two faculty members from the humanities and law, a staff member, a public representative, and a student yet to be named.

In addition to Campbell, panel members from Stanford are Profs. Paul Berg, biochemistry; Stanley Cohen, clinical pharmacology; Edwin Good, religious studies; John Kaplan, law; David Korn, pathology; Robert T. Schimke, pharmacology and biological sciences; Bruce Stocker, medical microbiology; and Research Associate Lucille Rasmussen, infectious diseases.

Berg will be succeeded in 1977 by David A. Clayton, associate professor of pathology.

Panel members from outside Stanford are Mark Chatigny, chairman of the University of California Biological/Environmental Department, Naval Biomedical Research Laboratory at Richmond, and Richard Rosenbaum, a former Palo Alto city councilman and research engineer at Lockheed.

Ex-officio members are James C. Bitter, assistant occupational health and safety officer (Medical Center); Patricia L. Devaney, assistant to the vice-provost for research; and Anthony J. Sidlow, Stanford manager of health and safety.

STANFORD--Most patients who receive heart transplants at Stanford Medical Center return to competitive employment, but some have encountered hiring discrimination before finding jobs, according to a recent study.

Ninety-one percent of Stanford's cardiac transplant patients who survived six months or more after their surgery have successfully returned to employment, to retirement by choice, or to student or homemaker status, according to the study published in the current Journal of the American Medical Association.

Half of those who returned to fulltime work resumed positions they had previously held and retained on disability leave during the transplant period. Others returned to self-employment.

A remaining five patients were successful in finding new employment postoperatively, but at lower salaries then those held preoperatively.

"The hiring discrimination often experienced by cancer patients and kidney transplant recipients appeared to be expressed even more strongly against cardiac recipients," according to Lois K. Christopherson, chief social worker in the transplantation program; Dr. Randall B. Griepp, assistant professor of cardiovascular surgery, and Dr. Edward B. Stinson, associate professor of cardiovascular surgery.

Fifty-six patients who survived six or more months after cardiac transplantation participated in the the study. Fifty-one were classified as successfully rehabilitated, defined as physically and psychologically able to lead active lives, performing tasks like those before their severe cardiac disease.

Four of the patients retained substantial physical disability, and one experienced psychiatric disability.

All patients selected as potential cardiac recipients at the Medical Center had an estimated life expectancy in the range of weeks to months.

Potential recipients were carefully screened not only for severity of illness but also for medical or psychosocial problems that might deter rehabilitation.

"There should be reasonable expectation that additional time gained by transplantation would be meaningfully used by the patient rather than be perceived as simply an extension of the dying process," the author said.

-more-

A notable feature of the rehabilitation of almost all recipients, said the authors, "was an intense sense of personal accomplishment and an awareness of expanded capacity for the enjoyment of living.

"Activities that before had been taken for granted assumed new meaning because of recipients' heightened sensitivity to the significance that each day of life held for them."

Foremost among adjustment tasks was coping with the new status that often generated increased attention.

Although at first attractive, this attention was "soon found to be superficial and to interfere with the cultivation of other, more meaningful roles."

The authors report that most patients and their spouses experienced more open communication as a result of transplantation, and considered the uncertain longevity in their family priorities.

When they described their transplant experience to friends, they usually focused on the benefits rather than past and current risks.

Currently, Stanford transplant patients show 69 percent survival rate at one year, 60 percent at two years, 51 percent at three years, 45 percent at four years, and 40 percent at five years after transplantation.

STANFORD--A $30,000 grant in support of a new oncology day care center at Stanford University Medical Center has been awarded by the Fannie E. Rippel Foundation of Morristown, New Jersey.

The oncology day care center is planned as a self-contained unit on the lower level of Stanford Hospital, offering a comfortable home-like atmosphere for cancer patients.

The Rippel Foundation, long active in the medical and hospital field, was formed by J.S. Rippel, a New Jersey banker and financier, as a memorial to his wife.

Individual donors, as well as other organizational support, will help meet the projected $140,000 costs of the unit.

The new oncology facilities will be located in the current Emergency Services area of the Hospital when Emergency is relocated into the new wing of the Hospital early next year.

Currently approximately 9,000 patients from throughout the U.S. and many foreign countries are treated each year in the oncology clinic. Examination rooms and outpatient facilities are shared with other medical specialties.

Dr. Saul Rosenberg, professor of medicine and chief of the division of oncology, will be director of the new unit.

He notes that the new facility, one of the first of its kind, will better meet the special needs of oncology patients who do not need to be admitted to the hospital. Such patients may need to receive regular chemotherapy infusions, or need to be seen daily for brief injections and blood counts, then return home.

The new unit will contain several separate examination and treatment rooms, patient waiting and consultation rooms, a doctors' conference area and other laboratories.

A pharmacy will be included, where nurses may store and mix drugs that require special handling. A small laboratory for hematology work will permit immediate laboratory results and should decrease patient waiting time.

Private offices will be provided for social worker and clinic service representatives, to aid patients with emotional, personal and financial problems related to their diseases.

Design of the unit calls for a waiting area outside the mainstream of the general hospital and clinical activities, to insure privacy for patients and their families.

Suzanne Miller, clinical oncology nurse coordinator, says special attention will be paid to furnishing the area. "We want to offer a home-like atomosphere, a warmth that is not possible in the present facilities, where patients can share their feelings privately with those they know. A cancer patient needs everything we can do to make it easier."

STANFORD--New blood transfusion and coagulation laboratories are being constructed in the new wing of Stanford University Hospital with a $100,000 grant from the William Randolph Hearst Foundation

Dr Clayton Rich, dean of the medical school and vice president for medical affairs, designated the general purpose grant for use in construction of the new laboratories. It is expected they will be in use before the end of the year

The transfusion service, the largest in California, ensures the compatibility and safety of all blood and blood products transfused at the Hospital and at Children's Hospital at Stanford

The coagulation laboratory provides routine consultation on medical and presurgery patients as well as those with hemophilia Much work of the unit is performed for the intensive care unit, in identifying coagulation deficiencies in surgical patients, particularly those receiving open heart surgery

Past gifts of the William Randolph Hearst Foundation have supported Stanford student writing awards, the department of communications, and the Hoover Institute

STANFORD--Ten scientists pursuing careers in teaching and research at Stanford University School of Medicine have been named Andrew W. Mellon Fellows.

They will be supported in part by a $325,000 award to Stanford by the Andrew W. Mellon Foundation of New York "to assist young postdoctoral scholars of demonstrated achievement and exceptional promise to continue their advance toward careers in teaching and research."

The fellows were announced recently by Dr. Clayton Rich, vice president for medical affairs and dean of the school of medicine.

According to the Mellon Foundation, "The chief purpose of the grants is to help minimize the loss to medical education and to research in the basic medical sciences which is certain to occur if individuals...are forced by lack of support to turn to other careers."

Stanford is one of 15 private medical schools to receive such funds under the Mellon Foundation Program. Stanford received a similar three-year grant from the Foundation in 1973.

The designated fellows are.

--Dr. Paul R. Cipriano, assistant professor of radiology, who is studying the structure and function of the middle muscular layer of the heart in normal and diseased states.

--Dr. Leslie J. Dorfman, assistant professor of neurology, who is studying the electrical activity of the nervous system in normal and certain disease states such as multiple sclerosis.

--Dr. Donald R. Goffinet, assistant professor of radiology, who is studying the effects of anticancer drugs and radiation therapy on cancerous tissue and spinal cord function.

--Dr. Mark Hilberman, assistant professor of anesthesia, who will be studying postoperative renal function to identify a pattern which leads to renal failure after cardiac surgery. He is also studying the interaction between muscle relaxants and inhalation anesthetics to determine the length of the two drugs' interaction following surgery.

--Dr. Ronald Levy, assistant professor of medicine (oncology), who is studying the relationship between immunology and cancer, particularly in human lymphomas and leukemia.

--Dr. Paul Pitlick, assistant professor of pediatrics, studying the exercise tolerance of children with congenital heart defects, especially following cardiac surgery.

--Dr. David J. Schurman, assistant professor of surgery (orthopedics), who is looking at mechanisms which cause arthritis and other inflammations of joints which may lead to new methods of treatment.

-more-

222--Andrew W. Mellon Foundation Grants

--Dr. Gerald Silverberg, assistant professor of surgery, who is working on a monitor to measure the production of intracranial pressure.

--Douglas Wallace, Ph.D., assistant professor of genetics, who is studying genes found in human cells which are important to respiration and certain inherited diseases.

--Dr. Roger Winkle, assistant professor of medicine (cardiology), who is studying the clinical effectiveness of drugs for the treatment of cardiac rhythm disorders.

FOR IMMEDIATE RELEASE

STANFORD –

Dr. William H. Northway, Jr., has been promoted to professor of radiology and pediatrics at Stanford University School of Medicine.

Northway is director of the Diagnostic Division and associate chairman of the Department of Radiology. His professorship, which is effective Jan. 1, was announced by Dr. Clayton Rich, vice-president for medical affairs and dean of the school.

A graduate of Stanford with a B.A. in 1954, Northway also received his M.D. from Stanford in 1957. He interned at New York Hospital (Cornell University) and completed his radiology residency at Stanford in 1961.

Northway was a James Picker Foundation scholar in radiology in 1963-66, and in 1963 he was at L'hopital des Enfants Malades in Paris. In 1965-66 he was voted the best pediatric instructor by the pediatric resident staff. He was also a Stanford University Fellow in 1972-75.

Northway has concentrated his research in the area of newborn lung disease, particularly pulmonary oxygen toxicity in newborn infants. He has written numerous medical articles and book chapters.

Northway's father, the late Dr. William H. Northway, Sr., also received his M.D. from Stanford Medical School.

The senior Northway served as chief of clinics, assistant dean of the Medical School, and acting physician-superintendent of the old Palo Alto-Stanford Hospital. He also served on the Hospital's governing board. He died in 1960.

The Big Game Medical Alumni Reunion, sponsored by the School of Medicine and the Stanford Medical Alumni Association, is planned for Friday, Nov. 19.

Morning postgraduate education courses in Room M112 will feature Dr. Stanley N. Cohen, professor of medicine, who will speak on "Genetic Manipulation of Microorganisms," and Dr. Abraham White, consulting professor of biochemistry, who will talk about "Prostaglandins: Biochemistry and Clinical Implications."

A noon reception and luncheon for alumni, associates, faculty, and spouses is planned for the Holiday Inn, Palo Alto. Featured speaker will be Dr. David S. Rubsamen, with the topic "The Malpractice Crisis: Turnaround in 1977?" Reservations are necessary for the luncheon.

A spouses' program in the morning includes a visit to the Myra Keen exhibit of shells in the Geology Building and an address by Dr. Robert L. Kovach, professor of geophysics, on earthquake prediction.

STANFORD--Dedication ceremonies for a new laboratory to study the effects of disease on tissue and other skin problems will be held at 12:30 p.m., Saturday, November 13 at Stanford University Medical Center.

The new facility will be known as the Irving B. Wershaw Dermatology Research Laboratory, according to Dr. Eugene Farber, chairman of the Department of Dermatology.

The laboratory will be equipped with an electron microscope and will be used for dermatology research as well as teaching.

Irving Wershaw was board chairman of Dome Chemicals, Inc. of New York and a vice-president of Miles Laboratories before his death in 1963. Dome, founded by Wershaw in 1939, made prescription medicine for skin disorders. The company was acquired by Miles Laboratories in 1959.

"Mr. Wershaw," Farber said, "was a very well-known and well-loved individual in the fields of dermatology and pharmacology." He had a collection of more than 2,000 autographed photographs of dermatologists and allergists whom he knew.

Mrs. Lona Duval Wershaw of New York City has given the dermatology research laboratory to Stanford University Medical Center in memory of her husband.

STANFORD--Stanford University School of Medicine may reject several hundred thousand dollars of federal funds on principle to avoid federal intrusion into its admission procedures.

"I believe universities must not compromise if they are to remain free academic institutions," said Dr. Clayton Rich, vice president for medical affairs and dean of the school.

In a letter circulated to faculty and students seeking their opinions, Rich said that giving in on this issue "could be unwise and counter to important academic principles."

The problem stems from a new law which sets conditions under which medical schools would be eligible for basic educational support. One provision requires schools to reserve places for Americans who have failed to gain admission into U.S. medical schools and now are studying medicine abroad.

The Department of Health, Education and Welfare is to set the rules for their admission to schools in this country. The problem, Rich said, is over having the university agree that the government and not the faculty set these rules.

"I believe we should not accept these provisions," wrote Rich. "This (law) compromises two fundamental academic decisions, the criteria for admission and selection of students.

"These are among a group of decisions which also includes criteria for faculty appointments, the curriculum, awarding of degrees, and content of scholarly activity which the university must not yield."

Rich said Stanford could receive up to $800,000 in capitation support. In addition, the law provides federally insured student loan support which would supplement what is now available.'

Last year the federally insured loan program accounted for 40 percent or $556,000 of the accumulated debt of Stanford medical students, he said.

Another condition in the law creating residency controls sets requirements for the number of physicians that could be admitted for training in the specialties. The mandate is that 35, 40 and 50 percent of all first-year residencies be in primary care (general internal medicine, general pediatrics or family medicine) for the three successive years beginning in 1977.

"I have reservations about this provision," said Rich, "but do not take the position that we should reject it on principle. That is because interns and residents are not matriculated in a university degree program and because the provisions clearly are intended in the public interest."

Rich said the initial faculty reaction to his letter has been strongly favorable.

-more-

A final decision, however, will not be made for several months until HEW issues its regulations and their effect on the admissions process is clear. Rich said he hopes that Congress would amend the law.

Last month Stanford University President Richard W. Lyman echoed similar sentiment before the Academic Senate.

"The issue is not whether the numbers involved will turn out to be large or small," Lyman said. "The issue is one of principle: a university medical school's right to establish its own admissions process, and to treat all applicants evenhandedly."

The New York Times reported Sunday that Yale Medical School may lose $1.5 million in capitation and grant support if it refuses to set aside places for U.S. foreign medical graduates.

Yale President Kingman Brewster called the action "an outrageous federal intrusion upon academic self-determination," according to the Times.

STANFORD--Almost half the patients hospitalized for heart attacks or coronary surgery in six San Jose-area hospitals, including Stanford, are not aware they have a disease involving the arteries of the heart.

Eighty-three patients at Stanford Hospital, O'Connor Hospital, El Camino Hospital, Good Samaritan Hospital, Community Hospital of Los Gatos-Saratoga and San Jose Hospital completed a questionnaire designed to test their knowledge and attitudes about heart disease before being discharged from the hospital.

Pat Barbarowicz, R.N., of Stanford's Cardiac Rehabilitation Program, who heads the study, said the questionnaire was a first step in developing an education program for hospitalized heart patients.

She explained that present patient education in hospitals is sporadic. A more effective and efficient teaching tool, such as audio-visuals, is needed. Barbarowicz also feels time for patient education should be provided in the nursing schedule and nurses should be trained to teach patients.

She said that by increasing patients' understanding of disease, the number of hospitalizations may be reduced. The hospitals' initial outlay for educational materials and commitment of staff may be justified by future savings, she said.

The study demonstrates that unstructured teaching programs now under way in some hospitals do not appear to be effective. Twenty-nine of the 83 patients tested received some in-hospital education about heart disease, yet did not do significantly better on the questionnaire than those who had no teaching.

Patients under fifty scored highest on the test. Educational level, social class and sex had little to do with how much the patients knew about their disease.

The patients in the study took a multiple-choice quiz before leaving the hospital. They were asked questions about cholesterol, exercise, smoking, diet and the structure and function of the heart.

Although the average score on the test was 63 percent, Barbarowicz said the scores could be higher with more effective teaching.

Beginning in January she will continue her study, funded by a grant from the American Heart Association, with an audio-visual program on heart disease for patients at Stanford and three other local hospitals. She will determine if people really learn from such a program, and more important, whether their attitudes and behavior change with increased knowledge.

FOR IMMEDIATE RELEASE
STANFORD –

Dr. Paul Bruce Beeson, professor of medicine at the University of Washington School of Medicine in Seattle, will deliver the seventh Louis and Dorothy Kovitz visiting professorship lecture at Stanford School of Medicine on Wednesday, Nov. 17.

Dr. Beeson's topic will be "Some Personal Views on American Medical Education and Practice," at 4 p.m. in the new Fairchild Auditorium of the Medical School.

Physicians and other health professionals in the community are invited to attend.

Dr. Beeson plans to discuss not only issues of the rising costs of medical care and the maldistribution of doctors in this country, but also his experiences in the British National Health Service.

His interests have been in infectious diseases and general medicine, and between 1954 and 1974 he served as Nuffield Professor of clinical medicine at Oxford University, England.

The Kovitz lectureship was established in 1969 by Dr. and Mrs. Kovitz of Los Altos to bring outstanding lecturers in medical and surgical fields to the Medical School.

FOR IMMEDIATE RELEASE
STANFORD –

Members and guests of the Associates of the Stanford University Libraries will join in a "walk around" of three of the science libraries of the University at 3 p.m., Nov. 14.

Jack B. Pooler, chief librarian of the science department, will be the host. Highlighing the tour will be an exhibit of the original Klystron tube, invented by W.W. Hansen and the Varian brothers, on loan for the occasion to the Physics library.

Starting point for the tour will be at the Falconer library in Herrin Hall (Biological Sciences Building).

Falconer, physics, and Branner earth sciences libraries will be visited, with a reception and refreshments in the Branner library concluding the afternoon.

Reservations are required and may be made by phoning (415) 497-2016.

STANFORD –

Cancer researchers at Stanford University School of Medicine are successfully treating small surface tumors in animals by applying an old idea—heat.

Preliminary results must be interpreted with caution, say the researchers. But findings have been encouraging enough in treating tumors in mice, that trials are now under way on spontaneous tumors in dogs, cats, and other animals referred by veterinarians.

Clinical trials in selected patients may begin next year, according to Dr. George M. Hahn, associate professor of radiology, and Dr. Jane Marmor, assistant clinical professor of medicine (oncology).

Dr. Hahn discussed his work at a Radiation Therapy Oncology Group meeting recently in Buffalo. The group is developing protocols for 11 institutions that will be treating metastatic lesions with combined radiation and heat.

For the current animal studies, Hahn said, volunteer pets such as dogs and cats with diagnosed incurable tumors are needed. Deep-seated as well as surface tumors may be treated.

The animals are seen as outpatients, with ultrasound heat treatments given three times a week for two weeks.

According to Dr. Marmor good results have been obtained so far in achieving regression of some tumors in the animals.

"About 50% have response of the heated areas," she says. "Those with squamous cell cancers seem to do very well."

The researchers have reported that certain tumors heated locally in mice have been virtually "flattened" in 48 hours. Fifty to 100% have been cured within a week, with little or no damage to adjacent normal tissues.

Although the idea of using heat to treat tumors is not new, there has been a lack of methods to accurately apply the heat locally.

The Stanford team uses ultrasound and radiofrequency electromagnetic fields to heat the tumors. Specially designed needle probes inserted into the tumor sites provide constant monitoring of temperature.

Mice were treated for specific flank tumors at temperatures of 108°F to 110°F (43° to 44°C) from 10 to 40 minutes, using radiofrequency electromagnetic fields. Tumor cure rate was a function of temperature and of duration of heat exposure.

In the study, all mice were cured of their tumors when exposed to 44°C heat for 20 minutes or longer. Approximately 50% cure rates were achieved with five minutes exposure at 44°C, with ten minutes exposure at 43.5°C, and with 30 minutes exposure at 43°C.

A puzzling finding, says Dr. Hahn, is that during the treatment heat kills fewer tumor cells than radiation or chemotherapy. Yet tumors continue to regress until cure is accomplished.

The researchers are conducting further studies to determine if an additional mechanism, such as stimulation by heat-treated cells of an immune system, could be responsible for rejection of the tumor.

Hahn feels that "radiofrequency and ultrasound heating may prove to be useful in the treatment of some malignancies even before we understand in detail the biology of thermal cell and tumor inactivation."

The current research is supported primarily by the National Cancer Institute.

(ADVANCE) FOR PM RELEASE MONDAY, NOVEMBER 8, 1976

STANFORD –

-Stanford Medical School researchers have succeeded for the first time in recording electrical signals from within nerve cells of the human brain.

The new development, said the researchers, will pave the way for study of single nerve cells to increase understanding of brain disorders such as epilepsy.

Drs. David Prince and Philip Schwartzkroin reported their research Monday, November 8, at the meeting of the Society for Neuroscience in Toronto, Canada. Details of their work also appear in the current issue of *Brain Research,* a scientific journal.

"Most of our knowledge about nerve cell function has been obtained from animal experiments," said Prince, professor and chairman of the Department of Neurology. "It has been impossible to study important questions such as the function of nerve sell membranes and the details of communication between cells in man."

Information about disorders in nerve cell function in conditions such as epilepsy has also been derived from animal studies, Prince added.

By applying newly developed techniques, and microelectrodes with glass tips smaller than 1/25,000 of an inch, the Stanford researchers recorded electrical signals from within nerve cells in small pieces of brain removed from patients undergoing operations for epilepsy and other disorders.

Prince explained that the brain tissue used in the research had to be removed as part of the operation for the disease. The experimental studies in no way affected the patients' surgical treatment.

The researchers placed bits of the brain tissue in a special chamber bathed by a solution containing sugar, salts, and oxygen so that nerve cells remained alive for hours.

The microelectrodes were then sunk into the nerve cells whose size averages .04 millimeters. The electric signals generated from within each cell are amplified and displayed on an oscilloscope screen or stored on tape for replay.

The technique can also be used for detailed studies of responses of nerve cells to drugs used in treatment of neurological disorders, said Prince.

STANFORD--Stanford University Hospital's successful Pre-Hospital Care Program for Paramedic Training has been expanded and now includes training in different parts of the San Francisco Bay Area.

Training is underway at Los Medanos Community College in Contra Costa County for 24 persons, most of whom are employees of ambulance companies or fire departments in that county.

Similar training through the Stanford program likewise will begin early next year in Marin County for a group of firefighters in the Novato and Marin fire districts.

According to Dr. Michael Eliastam, director of Emergency Services at Stanford Hospital and paramedics program director, the goal is to train approximately 100 paramedics in the next 12 months. Almost all of them are expected to work in emergency care programs in the Bay Area.

Eliastam explained that the paramedics training was recently decentralized in order to take the "skill and expertise of the Stanford program to remote communities while utilizing the resources and facilities available in those communities."

Students receive classroom training from Stanford instructors and local community physicians. The students then train in community hospitals under the supervision of those local physicians and nurses, as well as from the Stanford staff. They also receive practical experience by performing as paramedics (under supervision) in the field.

After completing the course, students must be certified by the county health officer in order to perform as licensed paramedics in that county.

Since the paramedics training program was initiated at Stanford Hospital in 1973, most of the training has been conducted at Stanford. Seventy-eight students, including two women, have graduated from the three paramedics classes held to date.

This is the first time that all of the paramedic training will be held in individual Bay Area communities where the paramedics are expected to work.

Eliastam noted: "We are attempting to see whether it is possible to decentralize a highly intensive program. Up to now, communities have found it difficult to obtain funds and to set up training programs for the small number of paramedics that each needs."

While paramedic training will begin in Marin County early in 1977, similar classes will also be underway at Stanford Hospital to train paramedics for Santa Clara and San Mateo counties.

STANFORD--Robert Fisher, a sixth-year medical student at Stanford University Medical School, has been named co-winner of the Hans Berger Award by the American Electroencephalographic Society.

The award honors one of the early researchers of brain waves in man. It is made annually to the young researcher whose work represents an outstanding contribution to the understanding of brain waves.

Fisher obtained his Ph.D. in neurological sciences at Stanford in June. He is now in clinical training for the M.D. degree. Enrolled in the Medical Scientist Training Program at Stanford, Fisher hopes to combine his interests in clinical care and in research.

Working in the laboratory of Dr. David A. Prince, chairman of the department of neurology, Fisher studied the neurophysiology of petit mal, one of the more common forms of epilepsy. He studied the relationship between the activity of individual brain cells and the surface EEG waves commonly used to diagnose epilepsy.

The experiments will be published in the scientific journal, Electroencephalography and Clinical Neurophysiology.

Fisher is from Fort Lauderdale, Florida, and received his B.S. degree from California Institute of Technology in 1971.

STANFORD--Dr. John A. Collins, an expert on traumatic shock and blood replacement, has been named professor and chairman of the department of surgery at Stanford University School of Medicine.

Collins' appointment will be effective April, 1977, according to Dr. Clayton Rich, vice-president for medical affairs and dean of the School of Medicine.

Currently a professor of surgery at Washington University in St. Louis, the 43-year-old surgeon was responsible for organizing the Army surgical research team in Vietnam which studied shock and derangements of blood clotting mechanisms in wounded personnel.

Collins' research in the battlefield helped define basic mechanisms of the body's response to severe injury, and are valuable to physicians responsible for the care of severely ill patients.

"Dr. Collins is expected to play an important role in the continuing development of surgery at Stanford," said Rich. "Rated a superior teacher by both students and residents, he is also recognized nationally as an excellent clinical surgeon and administrator."

Collins will succeed Dr. James B.D. Mark, professor of surgery and acting department chairman for two years.

A native of New York City, Collins received his undergraduate education at Fordham in 1955, his medical degree from Columbia University, College of Physicians and Surgeons in 1959, and completed his residency training in surgery at Columbia-Presbyterian Medical Center, New York, in 1965.

As a captain in the U.S. Army Medical Corps from 1965 to 1967, he served in the Department of Experimental Surgery at Walter Reed Army Institute for Research, and as chief of the U.S. Army Surgical Research Team in Vietnam.

He presently serves on the editorial boards of three prestigious journals in the field of surgery as well as major committees including the expert panel on review of blood and blood products of the U.S. Food and Drug Administration, and as chairman of the Pre- and Postoperative Care Committee of the American College of Surgeons.

Collins and his wife, the former Mary Julia Sheil, are the parents of four children.

STANFORD--Dr. Oleg Jardetzky, professor of pharmacology at the Stanford University School of Medicine, has been named recipient of an Alexander von Humboldt Award.

The award of $15,000 recognizes Dr. Jardetzky's pioneering work on the application of nuclear magnetic resonance to the understanding of protein structure and dynamics. It will be presented at a ceremony in Bonn, Germany, February 20, 1977.

Dr. Jardetzky is currently on sabbatical leave at Oxford University. The Stanford laboratory which he directs was among the first to introduce the use of the technique which allows a close-up view of nature.

The method of nuclear magnetic resonance makes it possible for researchers to pinpoint all the atoms in a complex protein molecule. Moreover, it allows them to observe exactly how the atoms move through space and time.

Dr. Felix Bloch of Stanford and Dr. E. Purcell of Harvard first described the phenomenon of nuclear magnetic resonance in 1945.

Dr. Jardetzky is a graduate of Macalester College, St. Paul Minnesota, and holds M.D. and Ph.D. degrees from the University of Minnesota. He has held appointments at the California Institute of Technology, Harvard University, and the Merck Institute for Therapeutic Research.

The Alexander von Humboldt Foundation which made the award was created in 1860 under the Board of Trustees of the Prussian Academy of Science in honor of Naturalist Alexander von Humboldt. Its objective is to encourage international academic cooperation.

The foundation was reconstituted in 1953 under the auspices of the government of the Federal Republic of Germany. Its awards program for senior U.S. scientists was inaugurated in an address at Harvard in 1972 by Willy Brandt, then West German chancellor.

STANFORD--Divorced parents involved in disputes over the custody of their children can now be helped by a new service established by the Child Psychiatry Clinic at the Stanford University Medical Center.

Called the Family Law Consultation Service, the new clinic makes recommendations to the courts in difficult custody and domestic legal disputes. It is believed to be the only one of its kind in northern California.

The custody clinic is staffed by a team of psychiatrists, psychologists and social workers who frequently work in consultation with lawyers.

The work of the clinic is detailed in the current issue of The Healing Arts, a publication of Stanford University Medical Center. The issue describes social service activities both at the medical center and in the community.

Social worker Ursula Moore, a member of the team, says, "This is a relatively new approach, because the awareness that this kind of service was necessary has been slow in coming."

She explains, "The intact family used to be thought of as the norm, but with today's high divorce rate that just doesn't exist as often as it used to." And when parents divorce, the children sometimes become the victims of their parents battles with each other.

Team members see the children and each adult involved in the situation. Adults can include parents, grandparents, present or future spouses of the parents, housekeepers, or any other adult who is significant in the children's lives.

The team also observes the present family unit and each potential one in a variety of settings to see how the individuals interact.

Each parent in the dispute must be willing to cooperate with the team to find the best solution to their custody problem, with the children's welfare their ultimate concern.

After careful consideration the team makes recommendations to the courts. But their responsibility doesn't end once their recommendations are made and they will explain their decision to the family.

"We help them understand and accept our reasoning for the sake of their children," Moore explains. "For some people this is sufficient and the battles over the children end."

Other people may require further therapy to help them adjust to the court's decision or to resolve the hurt and anger being directed into the custody dispute.

Moore admits "at times there can be no 'right' decision. The only thing you can do is to help everyone accept 'a' decision and not harm the children any further."

STANFORD--Dr. Ronald W. Davis, assistant professor of biochemistry at Stanford University School of Medicine, has been awarded an educational and research grant by the Camille and Henry Dreyfus Foundation.

Davis is one of 15 persons selected nationwide for the grants, which total $515,000. The grants are given to young faculty members with proven interest and ability in the fields of biochemistry, chemistry and chemical engineering. Nominees were selected by their own academic institutions.

Earlier this year, Davis, 34, was presented the Eli Lilly Award in Microbiology and Immunology. The Lilly Award is annually presented to an outstanding scientist under 35, and includes a medallion and $1,000.

The Dreyfus grant program was begun in 1969 upon recommendation of an advisory group whose chairman is Frederick E. Terman of Stanford.

A widely-recognized electron microscopist, Davis received a postdoctoral fellowship to Harvard, where he was involved in DNA and virus molecular biology.

In graduate work at California Institute of Technology (CIT), Davis developed the electron microscope heteroduplex method of investigating the sequence of nucleic acids, and analysis which has had significant uses in mapping sequences in DNA molecules.

Davis came to Stanford in 1972 as an assistant professor of biochemistry, where his research emphasis has been on gene manipulation.

Davis earned a B.S. degree in 1964 from Eastern Illinois University and undertook graduate studies at CIT, where he had an NIH (National Institutes of Health) predoctoral traineeship from 1964 to 1970.

STANFORD--The quality of surgical care in the nation's hospitals varies to such an extent from one hospital to another that it constitutes an important public health problem.

That is one finding in a continuing national study being conducted by investigators at Stanford University School of Medicine.

The researchers looked at the mortality rates from 15 surgical procedures in 1,224 hospitals. Procedures included cholecystectomy, gastric surgery for ulcer, repair of fractured hip, and amputation.

Their aim was to determine whether hospitals do have different rates of mortality and morbidity after surgery, and what hospital factors influence those rates. In their study they took into account differences in the initial condition of patients and type of surgery performed.

Preliminary findings from a study of 17 of the hospitals also suggest that various hospital characteristics predict differences in morbidity and mortality.

Researchers measured such aspects of hospital organization as the division of labor, variety of services offered, training of personnel, and methods of coordinating activities. Similar measures were used to examine the organization of surgical wards, operating rooms, medical staff and laboratory services.

The project is conducted by the staff of the Stanford Center for Health Care Research, who are members of the departments of anesthesia, sociology, and family, community and preventive medicine. Dr. William H. Forrest, Jr., associate professor of anesthesia, is director of the center.

The study began in 1973 with a grant from the National Academy of Sciences-National Research Council, funded through the National Center for Health Services Research, Department of Health, Education and Welfare.

-more-

222--Hospital Differences Study

Articles in the current issues of the journals Health Services Research, and Inquiry describe the technical designs of the study and initial findings.

These preliminary findings, for example, show that the differences in quality of care may be related to the amount of control exercised by the medical staff over its members at the time hospital privileges are granted.

Another important predictor of quality of care was the proportion of registered nurses involved in direct patient care.

The findings suggest that registered nurses have their impact on quality of care not only through direct patient care efforts, but also through the type of organization they create.

The amount of expenditures by the hospital per patient is also important. Results suggest that the greater the average expenditures per patient, the better the quality of care.

Forrest cautions, however, that data on hospital characteristics are still being analyzed, and results are tentative at this point.

The data do not reveal the identities of the individual hospitals. According to Forrest, "The aim was, and continues to be, not determining which hospitals are best or worst, but rather, what are the factors that influence the quality of care provided."

The Institutional Differences Study (IDS) was done as a follow-up of an incidental finding of the National Halothane Study that its 34 participating hospitals had markedly different overall surgical mortality rates, even after compensating for different surgical loads and patient characteristics.

The Halothane Study was begun in 1963 by the National Research Council to examine the relation between halothane, a commonly used anesthetic agent, and massive liver necrosis.

The IDS consists of two overlapping projects. One studied mortality rates for 14 operations on 314,060 patients in 1,224 hospitals. In the second study, data were specially collected in 17 of these hospitals for 8,593 patients in 15 surgical categories.

The larger survey used data from two sources: per patient data from the Professional Activities Study of the Commission on Professional and Hospital Activities; information on structural characteristics of hospitals is based on the annual survey conducted by the American Hospital Association.

In the 17-hospital study, data were collected on patients' conditions preoperatively, their general health status, and extent of their surgical disease. Patient questionnaires requested information about recent stressful events in their lives, their income level, insurance plans, and other data. Hospital data were obtained by interviews and questionnaires from administrative, nursing, and medical staff throughout the hospital.

As the studies continue, there will be further checks on the reliability of data sources and more complete analysis of hospital differences, the researchers said. Further analyses will be done to determine whether hospitals tend to have higher quality for certain procedures than for others.

STANFORD--Dr. Sophie Alway has been appointed coordinator for Women in Medicine at Stanford University School of Medicine.

Her appointment was announced by Dr. Clayton Rich, vice president for medical affairs and dean of the medical school.

Alway, who will work parttime at the new position, will help women who are working in training programs in the medical school. Currently, about 30 percent of Stanford Medical School's students are women.

Alway said her position is designed to help her "identify problems unique to the women here, to be a resource for information of special interest to women, and to be an advocate for their special concerns."

A 1941 graduate of Yale Medical School, Alway has served as coordinator of the Stanford program in human biology since its inception. She was formerly on the housestaff of the University of Minnesota Hospitals and at the University of Utah Hospital in Salt Lake City, specializing in pediatrics. She was also a pediatrician in the San Mateo County Health Department.

STANFORD--Gary Mecklenburg, associate superintendent of the University of Wisconsin Hospitals, has been named deputy director of Stanford University Hospital and Clinics, effective March 1.

The appointment was announced by Paul B. Hofmann, director of the Hospital and Clinics. The deputy director position had been vacant since Hofmann, who held the post from 1972 to 1974, was appointed to his current position.

Mecklenburg, 30, has been associated with the University of Wisconsin Hospitals in Madison since 1970, serving as associate superintendent since March 1976, assistant superintendent, and administrative assistant.

In 1974 he was recipient of the "Harold M. Coon, M.D. Award of Merit" of the Wisconsin Hospital Association, as Wisconsin's Young Administrator of the Year.

He has served as administrative extern at Presbyterian-St. Luke's Hospital in Chicago, and admitting officer at Central Dupage Hospital in Winfield, Illinois.

A native of Glen Ellyn, Illinois, Mecklenburg received his master's degree in business administration from the University of Chicago in 1970, and his bachelor's degree in anthropology from Northwestern University, 1968.

He and his wife Lynn have two children, ages 2 and 3 years.

STANFORD--Two public meetings dealing with recombinant DNA technology and its potential benefits and risks have been scheduled at the Stanford University School of Medicine January 31 and February 1.

The meetings are being co-sponsored by the University's administrative panel on recombinant DNA molecules and the Academic Council's committee on research.

The 12-member panel was formed last October to monitor and maintain safeguards for research on recombinant DNA at Stanford. It includes a public representative and an outside expert on biosafety.

Dr. David S. Hogness, professor of biochemistry, will speak at the first meeting January 31 at 8 p.m. in Room M114 of the Medical School. He will focus his remarks on what recombinant DNA research involves and why it is of interest to biomedical investigators.

The meeting, February 1 (same site and time) will be an open forum for interested members of the University and local community. The program will consist of questions and viewpoints on potential benefits and risks associated with the use of recombinant DNA technology.

Those interested in speaking at the February 1 meeting should submit a brief written notification to Anthony J. Sidlow, Department of Health Physics, Encina Hall.

The technique of genetic recombination involves transplantation of genes from one species to another in a form they can be easily studied. It can be done in such a way that the recombined genes can be reproduced in a host bacterium.

By combining genetic material from different species--such as humans and bacteria--new opportunities are provided for studying human genes. For example, recombinant DNA technology may allow production of scarce substances which can be used in treating human diseases.

Since this technology was developed four years ago, scientists have expressed concern about potential dangers associated with it. For example, genes responsible for certain human diseases could be reproduced in an uncontrollable fashion in bacteria.

As a result, scientists involved in recombinant DNA research agreed to place a voluntary moratorium on the research until federal guidelines could be established to insure the safety of research personnel and the public.

Last July the National Institutes of Health (NIH) issued the guidelines based on recommendations submitted by a panel of nationally-recognized scientists in the field, including Dr. Hogness.

Stanford is among many institutions that have adopted these research guidelines involving recombinant DNA molecules.

FOR IMMEDIATE RELEASE

STANFORD –

Citing disturbing public trends and federal policies toward medical education, a Stanford committee has recommended steps that would bring Medical School tuition in line with other educational programs of the University.

"It would be wise and defensible to have tuition payment assume a larger portion of the cost of medical education," said the committee in a report released Wednesday, Jan. 19.

The committee on tuition policy of the School of Medicine was headed by Dr. Lewis Aronow, former professor of pharmacology, now in Bethesda, Maryland.

The present tuition in the Medical School, which compares favorably with Harvard, Yale, Columbia, and other schools, is $4,470 per year. It will go up to $4,932 in the fall.

The committee did not set a dollar value for future tuition increases, but made these points:

"The cost of education per medical student at Stanford, estimated from 1972-73 data, ranges between $13,500 and $21,200 per year. Only 14 to 23 percent of the cost is recovered through tuition.

"By comparison University undergraduate programs recover 50% of their costs from tuition."

The remaining 77 to 86% of the Medical School's income comes from federal instructional grants, clinical income, endowment, and gifts.

The gap between revenue and expenses for the Medical School is growing and will continue, the report said. It is clear tuition revenues will materially raise the amount of funds the School needs.

But even that will not be enough, the committee said, because it allows a 1.2% increase in income needed to maintain the quality of medical education offered at Stanford.

Tuition increases may have to be coupled with other methods of fiscal management to meet the School's goals. Included are reinvestment of savings, increased professional income, and reduction in expenses.

The committee expressed concern that tuition increases in the future might restrict medical education at Stanford to children of the wealthy.

To offset this, the present policy which promises all admitted medical school applicants financial assistance to see them through their careers at Stanford should continue, the report said.

The committee set four constraints for determining future tuition increases:

* timing and magnitude of the increase should not have a major effect on currently enrolled students.
* the increase should not be so great as to lessen Stanford's competitive position for high quality applicants.

(more)

tuition 2-2-2

* as tuition rises there should be commensurate efforts to increase scholarship funds and loans.

* to the extent that outside funding is still available, it may be possible to slow down the pace of tuition increases.

The committee questioned whether the Medical School should comply with recent regulations which set forth conditions for federal educational support.

One of these requires medical schools to set aside a percentage of residencies in primary care. Another involves persuading a certain number of admitted applicants to agree to practice in the National Health Service Corps in underserved areas in exchange for scholarships.

"Coercion of the student body to make premature professional judgments was undesirable," the committee said. "And the School does not want to be put in a position of restricting admission to applicants willing to make such commitments."

The report added, "Stanford's reputation is for high quality research and patient care and for the production of specialists.

"An emphasis on primary care may be inappropriate and would change drastically the type of student Stanford attracts and the nature of facilities, faculty, and curriculum. Even in the context of a need for primary care physicians, the need for specialists will continue to exist."

If Stanford rejects these federal constraints, tuition should compensate for lost government instructional grants, the committee said.

The committee also recommended that:

* Graduate students working for the M.S. and Ph.D. degrees in the Medical School should continue to pay tuition levels set by the University's Graduate Division.

* Attention should be paid to developing a more cost-conscious approach to medical education.

* A plan for deferred tuition payments should be developed.

The report commented that physicians were among the highest paid professionals. "In light of this, taxpayers are becoming unwilling to subsidize medical students, feeling they should be able to borrow against their high future earnings."

FOR IMMEDIATE RELEASE

STANFORD –

Assembling a geometric puzzle can exert greater stress on the heart than either a personal interview or watching a videotape of erotic or traumatic scenes.

This is the conclusion of a study conducted by the cardiology rehabilitation program of the Stanford University School of Medicine.

Dr. Robert F. DeBusk, director of the program, and Dr. Margot McNeil, program psychologist, in a study prepared for publication this month, tested the effect of three presumably stressful stimuli on the heart rate and blood pressure of 20 patients six to seven weeks after they had suffered heart attacks.

The stimuli included interviews which probed issues such as sex, job, and reaction to the attacks, time-pressured attempts to assemble a geometric puzzle, and videotape viewings of erotic and traumatic scenes.

The tests were arranged in sequence and separated by periods of relaxation exercises.

No matter what the order of the stimuli in the sequence, said McNeil, the puzzle elicited the greatest increase in heart rate and blood pressure, followed by the interview. The videotape viewing had little effect. The relaxation exercises resulted in a decrease in the heart rate and blood pressure below the values recorded before the sequence was initiated, she said.

Puzzle assembly induces stress, said McNeil, because it is a self-imposed, self-competitive activity similar to the kind of pressure found at work.

The stressful element of the interview may be the patient-therapist interaction it involves. "This particular group (of patients) is very sensitive to social interactions and other people's expectations of them," she said.

Videotape viewing did not seem to affect the patients even when it depicted individuals having a heart attack. This may be because many patients deny that they've even had an attack, said McNeil, and therefore do not apply the viewing to themselves.

McNeil said that the project was one of the few which attempts to correlate psychological stress factors with physiological effects in heart disease. "We are interested in rehabilitation in the total sense of word," she said.

She said that the testing will enable the program to evaluate patients for their psychological readiness to go back to work. It gives them "a personal prescription" of how much stress they can take, she said.

Teaching patients body awareness and relaxation provides them with techniques to help them adapt to the situations which cause excessive heart rates, said McNeil.

"We suggest that instead of the ten-minute coffee break they take a ten-minute relaxation break," she said.

McNeil intends to expand the project to include follow-up studies of patients who have gone back to work.

The study was supported by the National Heart and Lung Institute, and by the George Frederick Jewett Foundation of St. Paul, Minnesota.

STANFORD –

Dr. John J. Conley, an internationally known specialist in cancer of the head and neck, will be the first annual George Kiperash Visiting Professor at Stanford School of Medicine, January 20.

Dr. Willard E. Fee, Jr., assistant professor of surgery at Stanford, says the professorship was established by Mr. Kiperash "to bring a national or international figure to the area for continuing education purposes and to enhance residency training at Stanford."

Dr. Conley is clinical professor of otolaryngology at Columbia University's College of Physicians and Surgeons. He is chief of the head and neck departments at Columbia-Presbyterian Medical Center, St. Vincent's Hospital, and the Pack Medical Foundation, all in New York. In addition, he serves in an advisory capacity to numerous hospitals in the New York area.

Conley will lecture on "Malignant Neoplasms of Salivary Gland Origin" in the Forum Room of the J. Henry Meyer Memorial Library on the Stanford campus, Thursday, Jan. 20, at 8 p.m.

Mr. Kiperash, a former Stanford patient, is a native of San Jose. He is in the ranching business and is associated with Modern Ice and Cold Storage Company of San Jose. Kiperash and his wife, Thelma, have four children.

STANFORD--A $40,000 grant to support an attempt to develop a leukemia virus vaccine for mice has been awarded to Stanford University School of Medicine by the San Francisco Foundation.

Dr. Henry S. Kaplan, D'Ambrogio professor of radiology, and his staff will try to modify a virus known to produce lymphomas and leukemias in mice in such a way that it is capable of acting as a vaccine, but without it tumor-inducing potential.

The fact that similar viruses are known to cause leukemias and lymphomas in cats, cattle and subhuman primates has suggested that human leukemias and lymphomas may also be due to a virus belonging to the same family.

This preliminary work with an animal vaccine could provide the basis for the development of a human cancer vaccine, if it is determined that such a virus is also the cause of human leukemia. However, extensive work must be done before a safe and effective cancer virus vaccine can be developed, Dr. Kaplan cautioned.

A pioneer in cancer research, Dr. Kaplan discovered in 1959 that leukemias and lymphomas in mice are actually induced by a latent leukemia-causing virus which is "triggered" into action by X-rays or certain chemicals.

STANFORD--The Max C. Fleischmann Foundation has awarded a $1.5 million grant to the Stanford University School of Medicine to support cancer research. The grant was announced by Dr. Clayton Rich, vice-president for medical affairs and dean of the medical school.

The grant will be used to complete and partially equip the third floor of the new Sherman Fairchild Center for the use of two groups involved in cancer research.

The addition to the Fairchild building will provide laboratory space for researchers in immunology and animal virology. The building already houses the Departments of Structural Biology and Neurobiology.

The immunologists, led by Dr. Hugh McDevitt, a pioneer in the investigation of genetic controls of the immune response, will continue to study how the normal immunological mechanisms of the body protect against cancer. They will also determine how modification of these mechanisms can possibly treat or cure cancer.

The animal virologists, part of the Department of Medical Microbiology, study the fundamental aspects of cell behavior. They will particularly look at the actions of viruses which produce diseases in animals, including man.

The potential contributions of these researchers to basic knowledge hold great promise for the prevention and cure of cancer, Dr. Rich said.

The Max C. Fleischmann Foundation has aided in the construction of a solar observatory on the Stanford campus and the Max C. Fleischmann Laboratories and the Laboratories for the study of Cardiovascular Diseases at the medical school.

STANFORD--Dr. Jack D. Barchas, a pioneer in the study of neurochemical aspects of psychiatry, will be the first holder of the Nancy Friend Pritzker Professorship in Psychiatry and Behavioral Sciences at the Stanford University School of Medicine.

The new endowed chair was established by a generous gift from the Pritzker Foundation of Chicago, announced Dr. Clayton Rich, vice-president for medical affairs and dean of the school.

The gift also will establish the Nancy Pritzker Laboratory of Behavioral Neurochemistry, Dr. Rich said.

Dr. Barchas and his associates are studying the biochemical and pharmacological aspects of depression and schizophrenia.

Nancy Friend Pritzker was a Stanford graduate, Class of 1970. She died in 1972. She was the daughter of Mr. and Mrs. Jay A. Pritzker of Chicago. Well known in the financial and investment fields, the Pritzker family has made notable contributions in support of education. Among these is the Pritzker School of Medicine of the University of Chicago.

Mr. Pritzker is a trustee of the University of Chicago and Michael Reese Hospital, and Mrs. Pritzker is a truestee of Grinnell College.

Dr. Barchas has been on the Stanford faculty since 1966. He was promoted to professor this year. His research has been concerned with chemicals which act as transmitters between nerve cells or as modulators of nerve cell activity.

These compounds, collectively called neuroregulators, are now recognized as being important in normal and abnormal behaviors including severe psychiatric disorders.

Dr. Barchas' work has demonstrated that adrenaline, originally thought to be formed by the adrenal glands, could also be formed in the brain. The work received the A.E. Bennett Award of the Society of Biological Psychiatry.

A native of Los Angeles, Dr. Barchas was educated at Pomona College and holds his medical degree from Yale Medical School. He received internship training at the University of Chicago's Pritzker School of Medicine in 1961.

STANFORD--A data bank to be used in the studies of liver disease will be established at Stanford University School of Medicine.

The data bank will be part of an inter-hospital cooperative program for liver studies funded by a three-year, $211,607 grant from the John A. Hartford Foundation of New York. The grant was announced jointly by foundation president Harry B. George and Dr. Clayton Rich, vice president for medical affairs and dean of Stanford Medical School.

Dr. Peter B. Gregory, assistant professor of medicine (gastroenterology) and project coordinator, said the liver studies will be conducted at Stanford, Santa Clara Valley Medical Center in San Jose and at Veterans Administration Hospital in Palo Alto. Two private physicians will also collaborate on the project.

The "major thrust" of the program is to organize a computer-based data bank for liver disease, Gregory said. Information from patient histories, physical examinations and laboratory tests will be fed into the data bank.

Gregory said the accumulated information will then be used in improving the care of patients with liver ailments and to support specific treatment trials. Acute and chronic hepatitis and cirrhosis are the major liver diseases that will be studied under the grant, Gregory noted.

The grant will also support continued education in the field of liver disease for physicians in training, as well as for practicing community doctors.

FOR IMMEDIATE RELEASE

STANFORD –

A prominent Soviet endocrinologist, now serving eight years in a Soviet labor camp, has been invited to lecture at the Stanford University School of Medicine and the University of California Medical Center in San Francisco.

Scientists at both institutions have asked the Soviet government to allow Mikhail Shtern to visit Stanford and UCSF this spring.

The invitation, the scientists said, was issued in the interests of furthering international exchange. The ultimate aim, however, is to win the release of the Soviet Jewish physician.

The letter from Stanford is signed by Dr. Arthur Kornberg, a Nobel Laureate in medicine and professor of biochemistry; and Dr. Daniel D. Federman, an endocrinologist and chairman of the Department of Medicine.

The invitation from UCSF was issued by Drs. Isidore S. Edelman, professor of medicine; Robert Jaffe, chairman of the Department of Obstetrics and Gynecology; and Melvin Grumbach, chairman of the Department of Pediatrics.

Shtern was invited to discuss his research on "Hormonal Mechanisms in Sexual Development in Man."

Letters about Shtern's invitation also have been sent to Dr. Boris Petrovsky, minister of health of the Soviet Union; and Soviet Ambassador in Washington Anatoly Dobrynin.

"We are writing to ask for your help in this matter in the interests of furthering international scientific exchange, a concern which we know you share with us," said the letter to Petrovsky.

Last year the Endocrine Society endorsed a resolution appealing to the Soviet government to release Shtern. "We find future scientific cooperative efforts obstructed by thoughts of Dr. Shtern's continued imprisonment," the resolution said.

In January, 90 concerned scientists, including Nobel Prize winners David Baltimore, Baruch Blumberg, Arthur Kornberg, Joshua Lederberg, Howard Temin, and George Wald signed an advertisement in the *New York Times* appealing for Shtern's release.

Shtern was educated at Vinnitsa Institute in the Ukraine. In 1947 he became head of the Endocrinological Center at Chernovtsi.

In 1974, when he was arrested, Shtern was director at the Vinnitsa Provincial Endocrinological Center.

According to a story in the *San Francisco Chronicle,* last December, Shtern's case attracted considerable attention in the West, when he was sentenced by a Ukrainan court on Dec. 31, 1974, to eight years at hard labor on charges of bribe-taking.

Jewish dissidents, however, said the charges against Shtern had been brought against him because his sons had applied to emigrate to Israel, and some accounts said that he, too, had sought an exit permit.

A book about Shtern entitled, *An Ordinary Trial in the U.S.S.R.,* will soon be published in the U.S., by one of his sons, a physicist who received an exit permit to go to Israel.

STANFORD--Dr. Marcolino G. Candau, former director-general of the World Health Organization (WHO), will speak on "Priorities in International Health" on Monday, February 28, at Stanford University Medical Center.

Dr. Candau's lecture at 4 p.m. in the Sherman Fairchild Auditorium is open to the public.

Candau was elected to the top position at WHO in 1953, and held the post for 20 years, developing strategies of health control now effective in many developing countries.

He is currently a visiting lecturer for the winter quarter at UC Berkeley. His Stanford lecture is sponsored by the Department of Family, Community and Preventive Medicine in the Medical School.

The recipient of many honors, Candau received the Leon Bernard Foundation Medal and Prize in 1974 from WHO for his contributions during that organization's formation.

He is well-known for his work in WHO's collaborative international research program, and for the expansion of environmental health programs.

He was born in Rio de Janeiro, Brazil, and served as assistant director of the Department of Health in the state of Rio de Janeiro. He has been professor of hygiene at the school of medicine there since 1938.

STANFORD--A Stanford researcher is looking for people who want to stop smoking and who won't mind if they don't enjoy it.

Dr. Brian Danaher needs healthy men or women who smoke at least a pack of cigarettes a day to participate in a smoking cessation study.

The clinical research will evaluate some techniques, such as smoke aversion, that may be unpleasant to participants. Danaher emphasizes there will also be enjoyable and informative aspects too, such as learning deep muscular relaxation and other skills to maintain nonsmoking.

The program is for people who want to stop smoking entirely, not just reduce the amount of smoking.

Participants should be able to attend five sessions, meeting once a week, each lasting not more than 30 minutes, at Stanford Medical Center.

The sessions will not be large group-sharing experiences, but individual discussions with the program consultant.

Danaher plans lots of homework for those who take part, including audio tapes and workbooks.

The aim of the study is not to test any specific new techniques, he says, but rather to evaluate whether the total program can be put into a format that doctors can use with their own patients.

Most of the techniques are already in use in academic medical centers throughout the country.

"We want to know whether we can develop a set of procedures a doctor can use when his patient asks, 'What should I do to stop smoking?' The doctor or other health professional would maintain close supervision of the patient throughout the program."

The techniques to be used "show promise of being the most effective methods available," says Danaher. They include some smoke aversion, such as smoking at different rates, which may cause some unpleasantness.

Participants will learn how they can breakup old smoking patterns by recognizing their particular situations that lead to smoking. They will develop skills to cope with smoking urges, and substitutes for smoking, such as other activities and exercise, says Danaher.

"We'll talk about how a person's thoughts can influence his smoking: rationalizing, proscrastinating, talking yourself out of particular behaviors, and being nostalgic about smoking."

Persons interested may call Danaher at 497-0323 between 10 a.m. and 4 p.m. Monday through Friday for the next two weeks.

The study is supported by a heart disease prevention fellowship to Danaher from the National Institutes of Health, and additional support from the American Cancer Society.

Participants will be charged an attendance deposit and a nominal fee. ###

EDITORS: Following is a commentary by Dr. Stanley N. Cohen, a molecular geneticist and professor of medicine at the Stanford University School of Medicine. He and his collaborators developed the basic techniques for recombinant DNA research, and in 1973 carried out the first successful gene transplantation experiments. His article is adapted from *Science*, Feb. 18, 1977, and is distributed with permission.

RECOMBINANT DNA: FACT AND FICTION

by Stanley N. Cohen

Almost three years ago I joined with a group of scientific colleagues in publicly calling attention to possible biohazards that might stem from certain kinds of recombinant DNA research. This technique for propagating hereditary material from diverse sources in bacteria was new and relatively simple. We were concerned that experiments involving some genetic combinations that seemed hazardous might be performed before adequate thought had been given to potential risks.

Guidelines already protect laboratory personnel and the general public against hazards associated with the handling of chemicals, radioisotopes, and disease-producing microorganisms. Because of the newness of recombinant DNA techniques, no guidelines were yet available for this research.

During the past two years much fiction has been written about "recombinant DNA research." What are the facts?

First of all "recombinant DNA research" is not a single entity. It is rather a *technique* used for a wide variety of possible experiments. Recombinant DNA techniques, like chemicals on a shelf, are neither good nor bad *per se:* certain experiments using these methods seem likely to be hazardous (just as certain experiments done with chemicals taken from the shelf will be dangerous). There is universal agreement that such recombinant DNA experiments should not be done.

Other experiments, such as taking apart a DNA molecule and using gene stitching techniques to put segments of it back together again, can be done without concern.

And there is the area in between—experiments for which there is no evidence of hazard, but no certainty that there is not a hazard. For these experiments, guidelines have been developed attempting to match a level of containment with a degree of *hypothetical* risk.

This is the single, most misunderstood point in the controversy about recombinant DNA research. Discussion of "risk" in the middle category of experiments relates entirely to hypothetical possibilities. It has nothing to do with expected consequences or even phenomena likely to occur on the basis of what we know. Unfortunately, this speculation has been interpreted as fact.

There is nothing novel about matching a level of containment with a level of anticipated hazard. Containment procedures used for disease-causing bacteria and viruses, toxic substances, and radioisotopes attempt to do this.

However, the measures used in these areas cover known hazards. In developing guidelines for recombinant DNA research we have attempted to protect ourselves against hazards not known to exist. This unprecedented act of caution is so novel that it has been widely misinterpreted as implying the likelihood of danger.

Critics of the research have made much of the fact that even if a particular recombinant DNA molecule shows no evidence of being hazardous now, no one can say for certain that it will not be dangerous some years hence.

(more)

This kind of statement is akin to saying that a vaccine that seems safe today *could* lead to infectious cancer in 20 years, an epidemic caused by a fatal traveler-borne virus *could* devastate the U.S. next month, or a new hybrid plant species *could* become an uncontrollable weed some time hence and destroy the world's food supply.

We have no reason to expect that any of these things will happen, but we are unable to say for certain that they will not happen. Similarly, we are unable to guarantee that efforts to influence the weather, explore space, modify crops, or cure disease will not carry with them the seeds for mankind's destruction.

Can we in fact point to any area of human activity where we can be certain there is no risk? Clearly we can develop plausible "scare scenarios" about virtually any type of research, and these would have as much (or as little) basis in fact as most of the scenarios involving recombinant DNA.

Unfortunately, the public has been led to believe that hazards described in these scenarios are likely outcomes of the research. "If the scientists themselves are concerned enough to raise the issue," goes the argument, "the problem is probably much worse than anyone will admit."

However, the simple fact is: there is no evidence that a bacterium carrying any recombinant DNA molecules poses a hazard beyond what we can predict from the known components of the recombinant. And experiments with gene combinations that pose known hazards are prohibited.

Yet the critics charge, "The time has come for scientists to abandon their long-held belief that they should be free to pursue new knowledge regardless of the consequences."

The fact is, no one has proposed that freedom of inquiry should extend to scientific experiments that endanger public safety. Instead, the history of this issue has been one of self-imposed restraint by scientists from the start, despite the conjectural nature of the risks.

Some critics have argued that construction of recombinant DNA molecules threatens the master plan of evolution. However, there is no reason to think that the evolutionary process is presently delicately controlled by nature.

To the contrary, man has long ago modified evolution, and biological evolution continues to be influenced by man. Primitive man's domestication of animals and cultivation of crops provided an unnatural advantage to some biological species and a perturbation of evolution.

The creation by man of hybrid plants and animals has resulted in the propagation of new forms of life that are not the natural products of evolution. In the microbiological world the use of drugs to treat bacterial infections and the use of mass immunization programs against viral disease have made untenable the claim of delicate evolutionary control.

One well-known critic of recombinant DNA research asks, "Have we the right to counteract irreversibly the evolutionary wisdom of millions of years. . . .?" It is this "evolutionary wisdom" that gave us the gene combinations for bubonic plague, smallpox, yellow fever, typhoid, polio, and cancer.

The acquisition and use of all biological and medical knowledge constitutes an intentional and continuing assault on evolutionary "wisdom." Is this the "warfare against nature" that some critics fear?

How about the benefits? Are they equally speculative or is there some factual basis for expecting them?

In the short space of three and a half years the use of recombinant DNA technology has led to important advances in basic knowledge. Using these techniques, we have begun to learn how genes of complex cells are organized into chromosomes and how gene expression is controlled. With this knowledge we can discover how defects in structure can alter gene function in human disorders such as cancer and diabetes.

On a more practical level, recombinant DNA techniques may enable the construction of bacterial strains that produce biologically important substances such as insulin and other hormones, or antibodies and vaccines to treat presently uncontrollable viral diseases.

We can expect recombinant DNA techniques to revolutionize the production of antibiotics, vitamins, and medically and industrially useful chemicals. And we can anticipate the development of antimicrobial agents that are not inactivated by drug-resistant bacteria.

(more)

Other benefits from this research in the areas of food and energy production are more speculative. However, even in these areas there is a scientific basis for expecting that the benefits will someday be realized.

The limited availability of nitrogen fertilizers and the potential hazards associated with their excessive use presently restricts the yield of certain crops. It would be possible, agricultural experts suggest, to use the techniques of gene transplantation to modify grains and other food crop plants so that they will not require nitrogen fertilizers for growth.

For years scientists have modified their heredity of plants by comparatively primitive techniques. Now there is a means of doing this with greater precision than has been possible previously.

It is ironic that some of the vocal opposition to this research has come from environmentalists. Yet the ability to manipulate microbial genes promises a more effective use of renewable resources for mankind's food and energy needs.

Even if hazards are speculative and the benefits are significant, wouldn't it be better to carry out the research under an added measure of safety? This is exactly what is required by guidelines issued by the National Institutes of Health. Most recombinant DNA experiments must be done under physical containment conditions at least as strict as those used for work with bacteria that cause typhoid fever and Asiatic cholera.

Other experiments require containment facilities of the type designed for the most dangerous natural viruses known.

Such conditions are required for recombinant DNA experiments in which the evidence of danger is nonexistent and the possibility of hazard is remote. Moreover, the use of biologically weakened bacteria reduces even further the chance of propagation of recombinant DNA molecules outside the laboratory.

These containment procedures have made it difficult for the public to appreciate that most hazards under discussion are conjectural. The safety measures are perceived as evidence that dangers from this research are clear-cut and imminent.

However, many billions of bacteria containing a wide variety of recombinant DNA molecules have been propagated in the U.S. and abroad without any known hazard. Most of these experiments were carried out prior to the stringent containment procedures now specified in the federal guidelines.

Nevertheless, one can validly argued that unknown hazards may remain. Conjecture has no limit; the studies that can be done to establish the absence of hazard are finite in number.

The public can reasonably expect a mechanism for dealing responsibly with hazards known to exist or which appear at all likely on the basis of known information. Beyond this, scientists can and should exercise caution in any new research activity.

Today, as in the past, there are those who would like to think that there is freedom from risk in the *status quo*. Yet, even the status quo presents unknown risks, as well as a large collection of known hazards. Humanity continues to be buffeted by ancient and new diseases, and by malnutrition and pollution; recombinant DNA techniques hold the promise of a partial solution to these problems.

We must ask, then, whether we can afford to let preoccupation with hypothetical risks limit our ability to deal with hazards that *do* exist. Let us distinguish vague fear of the unknown from fear that has some basis in fact.

STANFORD--Dr. Heinrich Rose, emeritus senior scientist in ophthalmology at Stanford University School of Medicine, has been name recipient of an Alexander von Humboldt Award.

The award recognized Dr. Rose's long career in physiological optics research, particularly the effects of visible light and laser radiation on the eye.

In conjunction with the award, Dr. Rose spent the past eight months in research at the University Eye Clinic, Essen, Germany.

The foundation which made the award is operated under the auspices of the government of the Federal Republic of Germany, and was created to honor naturalist Alexander von Humboldt. Its objective is to encourage international academic cooperation.

Dr. Rose received his M.D. from the University of Munich in 1933. He trained in ophthalmology, was a practicing ophthalmologist, and involved in optics research applied to aviation medicine with the German Air Force.

He was a researcher for the U.S. Air Force from 1945 to 1959, and has been associated with Stanford since 1961. He has been on the fulltime staff since 1966.

STANFORD--Men whose mothers took stilbestrol, a synthetic form of estrogen, during their pregnancy are being sought by Stanford University urologists for a study of the relationship between exposure to the hormone and the development of abnormalities in the reproductive system.

Drs. Robert Andonian and Robert Kessler of the Division of Urology at the Stanford University School of Medicine are conducting the study. Men who know they were exposed to the hormone while their mother was pregnant should contact the division concerning a free evaluation.

According to the physicians, a recent NIH-supported study at the University of Chicago found that genital abnormalities and pathological semen quality occur with a greater incidence in exposed males as compared to unexposed controls.

Twenty-six percent of the exposed males had genital abnormalities such as cysts in the area at the back of the testes, and underdeveloped testes compared to six percent of the controls.

The average value of the sperm count was about two times lower in the exposed group.

Severely pathological semen quality, determined on the basis of sperm count, motility of sperm, and physical abnormalities, occurred in twenty-eight percent of the exposed males, but not in any of the controls.

The combination of genital abnormalities and pathological semen quality was observed only in the exposed group.

No cancer was discovered in any of the males examined.

Until now abnormalities were thought to occur only in women who had been exposed in the uterus to stilbestrol.

Stilbestrol was administered in the early 1950's to prevent or decrease complications during pregnancy, and to correct deficiencies in the production of hormones by the placenta.

However, subsequent studies found that stilbestrol did not reduce the incidence of miscarriage, premature or postmature birth, or perinatal death (occurring at birth), and its use was discontinued.

In 1971, physicians at the Massachusetts General Hospital found a rare form of vaginal cancer in seven women whose mothers had taken stilbestrol during their pregnancy.

In a similar nationwide study in which Stanford has participated, 300 cases of the clear cell type carcinoma of the vagina have been reported. Two thirds of the women with cancer who had prenatal records had been exposed to stilbestrol in the uterus.

At Stanford, Dr. Eugene Sandberg, associate professor of gynecology and obstetrics, and his colleagues examined 499 exposed women. Two thirds of them "have some very minor anatomical variations of the cervix and vagina, benign 'badges' of stilbestrol exposure," he said.

None, however, had developed cancer. ###

STANFORD--New governing bylaws which clarify the authority of Stanford University Hospital's board of directors and the president of the University have been adopted by the Stanford University Board of Trustees.

The trustees took the action in their capacity as the general members of the non-profit hospital corporation.

The revisions, many of which were required by the Joint Commission on Accreditation of Hospitals and regulations of the State Department of Health, will not alter the present policies of the hospital, but they delineate the duties and responsibilities of the two governing bodies, said Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine.

The president of the university through his appointed chief executive officer will be responsible chiefly for the operation and management of the hospital.

The nine-member board of hospital directors will have authority over medical staff membership, and will advise the president through his designate, and the board of trustees on planning matters, budget, rates, and needs of the hospital.

The hospital board, as in the past, will be appointed by the general members and will continue to include at least three persons who are residents of Palo Alto and not employees of the hospital or the university.

Stanford University has a 40-year contract with the city of Palo Alto which gives priority for use of 370 beds in the 618-bed hospital to Palo Alto patients of community physicians.

None of the provisions of this contract are affected by the new bylaws, Rich said.

The medical staff will be self-governing with respect to the professional work performed in the hospital. Its bylaws and organization will be subject to hospital board approval, as required by law.

The hospital board will also hear appeals by members of the community staff when disputes regarding staff privileges and performance arise.

A joint committee of community and faculty physicians is currently drafting new bylaws for the medical staff, according to Rich.

STANFORD--A specific imported herbal medicine pill may cause lead poisoning according to doctors at Stanford University Hospital.

Persons taking Chrysanthemum-brand "Rheumatism Pills" and who have symptoms of lead poisoning, should contact their physician for examination and laboratory tests.

Drs. Johnson B. Lightfoote and H. Joseph Blair treated one patient recently for lead poisioning apparently caused by the pills. The patient, the only reported case of illness from the pills, is now recovering satisfactorily at home.

The "Rheumatism Pills," imported from Hong Kong, are sold in a box bearing a yellow and red label in Chinese. They are brick red, spherical, about 4 millimeters in diameter, about the size and shape of a pea.

Symptoms of lead poisoning, according to the doctors, include constipation, abdominal pain, muscle aches and weakness. Anemia and elevated levels of lead in the blood and urine are found in laboratory tests.

The pills are apparently taken as treatment for joint and muscle pains.

They contain 0.2 to 0.5 milligrams of lead per pill. The patient treated at Stanford had been directed to take 30 pills per day, and was receiving about 12 mg of lead per day Toxic accumulation can occur at an intake of less than 1 mg per day, say the doctors.

The San Francisco herbalist dispensing the pills was unaware of their lead content, according to John Rynd, director of investigations at the San Francisco district office of the Food and Drug Administration. FDA officials say the herbalist has contacted his patients who may have the pills.

Both the San Francisco Department of Public Health and the FDA have contacted herbalists and others in the Bay area who are most likely to have the pills, and report they have not found any.

In addition, the Hong Kong manufacturer is being advised of the problem, and all herbal medicines being imported will routinely be analyzed for lead content, according to the FDA.

STANFORD--Dr. Barry G.W. Arnason, professor and chairman of the Department of Neurology at Pritzker School of Medicine, University of Chicago, will present the first George A. Zimmermann Lecture on Feb. 11 at Stanford University School of Medicine.

Arnason will speak on "Immunological Aspects of Multiple Sclerosis." The lecture will begin at 5 p.m. in Room M-106 of the medical school and physicians and other health professionals in the community are invited to attend.

Arnason is widely recognized for his immunological studies of several neurological diseases, including M.S. Prior to assuming the chairmanship of the University of Chicago's Neurology Department last year, Arnason was associate professor of neurology (1971-76) at Harvard Medical School. He received his M.D. from the University of Manitoba in 1957.

The lectureship, which will be held annually, was established by the Stanford Neurology Department. It is part of a $500,000 gift by the late George A. Zimmermann for multiple sclerosis research and treatment at Stanford.

A longtime San Francisco businessman, Zimmermann died in late 1974. He bequeathed virtually all of his estate to various charities and for medical research.

STANFORD--Dr. James Dewey Watson, Nobel laureate and codiscoverer of the double helical structure of genetic material (DNA), is visiting professor at Stanford University School of Medicine during the Winter quarter.

Watson is professor of biology at Harvard University, and director of the Cold Spring Harbor Laboratory.

At Stanford he is delivering a series of lectures for graduate students on "The Transformed Cell," dealing with the nature of cancer cells.

Watson received the 1962 Nobel Prize in medicine with Britishers F.H.C. Crick and M.H.F. Wilkins, for discoveries concerning the molecular structure of nucleic acids and how genetic information is replicated.

He is the author of "The Double Helix" in 1968, and the text, "Molecular Biology of the Gene" now in its third edition. Watson holds the Eli Lilly Award in biochemistry, 1959, the Albert Lasker Prize, 1960, and the John J. Carty Gold Medal from the National Academy of Sciences, 1971, among others.

STANFORD –

The recently issued guidelines by the National Institutes of Health are not adequate to ensure the safety of recombinant DNA research.

This was the general consensus of a group of scientists and community members from across the country who presented their views on recombinant DNA Tuesday night, Feb. 1, in the Fairchild Auditorium of the Stanford University School of Medicine.

Nearly 500 people attended the forum, which was sponsored by the University's panel on recombinant DNA and the Academic Council's Committee on Research.

The purpose of the meeting was to discuss the risks involved in the controversial research that combines genes from different organisms in order to study heredity, and to allow the public to take its own look at the potential benefits and possible harm from the genetic research.

Dr. Richard Goldstein, a Harvard microbiologist, said that the guidelines cannot guarantee containment of genetically modified bacteria in the laboratory.

In most experiments, the guidelines specify the use of a weakened K2 strain of *E. coli* bacteria, which is "highly unlikely to survive out of the laboratory or to exchange DNA with other cells," said Dr. Paul Berg, professor of biochemistry at the Medical School.

But, according to Goldstein, the addition of genes from other organisms may confer on the *E. coli* the ability to survive.

"Literally tens of thousands of genes which have never been studied before are being put into *E. coli*. There's no predictability there, and that's the dilemma," he said.

Even if the enfeebled bacteria are unable to survive in the normal human, they may be able to infect people whose resistance is low.

"*E. coli* infections are increasing at a steady rate today in enfeebled hosts, such as the elderly, those with chronic disease, or those who have been treated with drugs which diminish the immune response," said Dr. Halsted Holman, professor of medicine.

He called attention to the danger of conducting recombinant DNA research close to hospitals. He said workers involved in recombination studies "walk through the wards everyday where those compromised patients are.

(more) 2/2/77

"Certain elements of prudence dictate that we ought to take a look at" the juxtaposition of low-immunity populations to recombinant DNA research.

Dr. Henry Levin, an economics professor in the School of Education, questioned whether physical containment specified under the guidelines is adequate.

Quoting from an article in *Science,* he said, "the incidence of laboratory-acquired infections was 5,000 in the last 40 years in laboratories with special containment facilities."

Berg argued the guidelines assign recombination experiments to various degrees of physical containment depending on the potential risks involved.

"Certain experiments, like the introduction of botulins or diphtheria toxin from virus into bacteria, are prohibited and can't be done anywhere in this country," he said.

Experiments between species not known to exchange DNA must be done under stringent conditions, he said. Laboratories must have double-door entrances, negative air pressure, and special air filtration devices.

For experiments between species which naturally exchange DNA, or "for which there is virtually no risk," less stringent conditions are required, Berg said.

Other speakers criticized the guidelines because they did not regulate research done by industry.

Dr. Leslie Grimm, a Mountain View biologist, expressed concern about commercialization in the area of recombinant DNA research before all the facts are known about its dangers.

"There are six major drug companies actively involved in this field," she said. "Applications for patents in technology development are pending. One biochemist has formed his own company to exploit the procedure commercially."

"The pharmaceutical industry is a highly profit-oriented and competitive one," said Mark Noble, a Stanford predoctoral student in genetics.

"I don't think they're going to follow the guidelines without being required by federal regulation," he said.

Holman said it was improper that Stanford and the University of California had filed application to patent the recombinant DNA procedure. "We cannot be credible as an institution if we stand to profit by the research," he said.

Some of the speakers thought the scientists should be responsible for the consequences of their findings.

But William F. Massy, vice-provost for research, said that consequences are becoming more difficult to see, because the complexity of the studies is increasing.

(more)

"We have tended to find that it simply doesn't work very well to try to predict all the things that could be done with the discovery," he said.

Attempts to classify all the possible ills and then use it as a justification to burn books will not further the cause of mankind, he said.

"That's a totally irresponsible position," remarked Mark Lappe of the state Department of Health.

"The fact of the matter is we now know how perfectly innocent quests for knowledge" can be used in harmful ways, he said.

Most of the speakers believed that more input from the public was needed for regulation.

David Thom, a member of the Stanford Alliance for Radical Change, said, "The control of recombinant DNA research is far too important to leave in the hands of an elite group of people who stand to profit from it."

"I simply do not trust the Harvards or the MITs or the Stanfords to police their own," said David Clem, a member of the Cambridge, Massachusetts, city council.

Clem said the NIH guidelines represented a conflict of interest. "An agency charged with promulgating research cannot be charged with regulating that research," he said.

He used Cambridge as an example of active participation by the public. The citizen's board was set up by Mayor Alfred E. Velucci to review recombinant DNA research conducted at Harvard and MIT.

"Don't shut the door on involving the public in a meaningful way," he said. "They are up to it."

Most speakers advocated a slowdown in research until the consequences and hazards can be more accurately assessed.

But according to Berg, the slow down has already begun.

"The guidelines seriously impede the progress of research. There are important experiments which can't be done today because of the guidelines."

He said that in the recombinant DNA matter scientists demonstrated they could provide the early warning system for alerting society to the potential benefits and risks of their discoveries. Accusations of self-interest, arrogance or even manevolance do little to encourage further efforts of that kind.

"I think it's reasonable to wonder if we haven't already squelched the concerned scientists of tomorrow," he said.

FOR IMMEDIATE RELEASE
STANFORD –

The likelihood of a hazardous accident occurring because of genetic manipulation research is as remote as the chance of being struck by lightning, a Stanford biochemist says.

Dr. David Hogness told an audience of more than 700 at Stanford School of Medicine Monday night, Jan. 31, that potential longterm benefits from such research may outweigh any possible dangers associated with it.

The public meeting was one of two cosponsored by the University's administrative panel on recombinant DNA and the Academic Councils committee on research, dealing with the potential benefits and risks of the technology.

Hogness is professor of biochemistry at Stanford, and helped to draw up guidelines for research with hybrid or recombinant molecules. The technique, developed in the last few years, permits scientists to join together genetic material (DNA) from bacterial and animal cells or viral sources in the laboratory.

Hogness said fears that some of the new kinds of molecules could escape accidentally and become established in the population, with unknown effects, are imagined fears and not based on facts.

"There is no data to demostrate that these random colonies (carrying recombined genetic material) have ever hurt anyone.

"Hundreds of thousands of clones, or recombinant molecules, have been handled in laboratories in the U.S., in Switzerland and in the USSR in the last three and a half years," he said, "and no one has been hurt."

An epidemic of drug-resistant bacterial strains in humans, said Hogness, is highly unlikely, since in most cases the new hybrids cannot compete with original strains occurring in nature, and would die outside the laboratory environment.

In addition, containment conditions in laboratories doing such work are extraordinarily tight, said the biochemist. Researchers must work under conditions similar to hospital laboratories dealing with infectious diseases like diphtheria.

Studies that call for inserting human DNA into bacterial strains are not possible now, he says, because the necessary containment facilities are not available. It is not likely that one could be built for at least two years, he indicated.

Hogness said the potential benefits for human health problems from such research could be "remarkable." He listed one such "nonspeculative benefit" would be the development of bacterial strains to supply medically useful materials, such as insulin. The technology for such a "straight-forward experiment," he said, is available now, though the process would take two to three years.

The technique of joining together genetic material from different sources, says Hogness, allows scientists for the first time to isolate segments containing a small number of genes. Investigators can then map where particular genes are located on chromosomes.

What can we learn from an isolated gene? "We have an enormous ignorance about how genes are regulated in higher organisms—how different ones are turned on and off.

"Many human diseases occur because of breakdowns in genetic regulation, such as in cancer, where cells no longer operate under normal processes of control. To fix such breakdowns, said Hogness, scientists must first understand the basic framework and what needs to be "fixed."

The meeting at 8 p.m. Tuesday, Feb. 1, in the Fairchild Auditorium, will feature a forum of speakers, including David Clem, city councilman from Cambridge, Mass., Dr. Richard Goldstein, Harvard microbiologist, and Dr. Halsted Holman of Stanford's department of medicine. Also scheduled to speak are Dr. Henry Levin, a psychologist, and Dr. Jack Frumin, a Stanford clinical professor.

FOR IMMEDIATE RELEASE

STANFORD –

Dr. Richard Lamerton, an advocate of the hospice concept of health care for the terminally ill, will present a public lecture Monday, April 4, at Stanford University School of Medicine.

Lamerton, who serves as director of studies at St. Joseph's Hospice and clinical assistant at St. Christopher's Hospice, both in London, will talk on "Hospice—Care of the Dying." His address will begin at 8 p.m. in the Sherman Fairchild Auditorium.

Hospice is a term revived from the Middle Ages which refers to facilities that provide spiritual, emotional and physical support for the sick and dying.

Lamerton, whose research has centered on pain relief, will speak on alternatives to hospital treatment and what patients in a hospice setting can expect as part of their care.

A medical graduate of St. Bartholomew's Hospital in London, Lamerton served as a family physician before joining St. Joseph's. He is chairman of the Human Rights Society of England and is author of the book *Care of the Dying* and coeditor of *The Hour of Our Death* with Dr. Sylvia Lack, who is medical officer to Hospice Inc. of Connecticut.

Lamerton previously lectured in the Bay Area in 1975 and again last year at hospitals, medical centers, and other medical and religious facilities.

"The hospice concept seems to be a reaction to the dehumanization of some areas of medicine," noted Dr. Count D. Gibson Jr., professor and chairman of the Department of Family, Community, and Preventive Medicine at Stanford. "It is an institution and organization committed to the support of the dying."

Gibson said there is a growing national interest in the hospice concept. "Lamerton will present a sharp challenge to some ideas of regular medical care," he added.

Lamerton will answer questions from the audience at the end of his address.

STANFORD--New administrative changes at the Stanford University Medical Center were announced Monday, March 28, by Dr. Clayton Rich, vice-president for medical affairs and dean of the School of Medicine.

John J. Schwartz, assistant vice-president and counsel for medical affairs, has been promoted to associate vice-president.

Peter J. Levin, an associate commissioner in the Department of Health, New York City, has been appointed associate vice-president for medical affairs.

The two changes, according to Dr. Rich, represent a realignment of duties previously held by Peter Carpenter and Schwartz who in his new position will take up additional responsibilities.

Carpenter, executive director of the Center, resigned last fall to become a vice-president of Alza Corporation in Palo Alto.

Rich said that Levin's responsibilities will be concentrated mainly on the Stanford University Hospital and Clinics and on administrative services that mainly support the hospital. Among administrators reporting to Levin will include the directors of the hospital, finance, and facilities.

Schwartz will be responsible for general nonacademic administration, including the office of personnel, legal affairs, and a new office of government relations.

Levin is a 38-year-old Harvard graduate, with a masters degree in public health from Yale University, and a doctor of science (medical care and hospitals) from the Johns Hopkins School of Hygiene and Public Health.

Before becoming associate health commissioner in New York, he served as executive director of New Haven Health Care, Inc., and acting executive director of the Bronx Municipal Hospital Center, New York.

He held positions in the Department of Health and Mental Hygiene in the state of Maryland, and was administrator of the Public Health Service Indian Hospital at Blackfeet Reservation, Browing, Montana.

In addition, Levin taught at Albert Einstein College of Medicine, New York University, and Yale.

Levin will assume his duties at Stanford April 27.

Schwartz, formerly a special assistant to Stanford University President Richard W. Lyman, was appointed counsel for medical affairs at the Medical Center in 1973, and to assistant vice-president for medical affairs in 1975.

A graduate of Cornell University, he received his law degree from Harvard in 1958 and obtained a Ph.D. in physics from the University of Rochester in 1965.

He practiced law in Phoenix, Arizona and taught physics at the University of Rochester before coming to Stanford in 1969 as assistant professor of physics. He was admitted to the California State Bar in December, 1974.

STANFORD--Dr. Arthur J. Atkinson, Jr., a noted clinical pharmacologist, will be the William N. Creasy Visiting Professor of Clinical Pharmacology at Stanford University School of Medicine during the week of March 28, 1977.

Atkinson will present the Creasy Memorial Lecture on the use of drugs for cardiac arrythmias at 8:30 p.m. on Thursday, March 31 in Room M-106 of the medical school. The title of his talk is "N-acetylprocainamide: Impact of an Active Metabolite on Procainamide Therapy."

The remainder of Atkinson's five days at Stanford will include medical rounds with professors nd the hospital's house staff, research and case conferences, and seminars at Stanford as well as at the Palo Alto Veteran's Administration Hospital.

Atkinson is associate professor of medicine and pharmacology and director of the clinical pharmacology unit at Northwestern University Medical School. His research has centered on antiarrythmic and anticonvulsant drugs with a particular interest in drug metabolism and the development of new methods to study drugs.

The Creasy professorship is sponsored by the Burroughs Wellcome Fund. Creasy, a graduate pharmacist who died in 1974, was President and Chairman of the Board of Burroughs Wellcome and Company for 23 years from 1945-1968. The program was established to further his goals for the advancement of clinical pharmacology as a discipline.

Dr. Clayton Rich, dean of the medical school, expects the visiting professorship "to provide a much wider recognition of the role of clinical pharmacology in medical teaching and practice at our school."

ADVANCE FOR RELEASE AFTER 11 A.M. TUESDAY, MARCH 22, IN CONJUNCTION WITH DR. DANAHER'S TESTIMONY.

LOS ANGELES –

A new program to help pregnant women stop smoking was described Tuesday, March 22, by a Stanford researcher in testimony before the American Cancer Society's National Commission on Smoking and Public Policy.

Hearings were held in the Federal Building in Los Angeles, the first of eight to be held across the country. Their aim is to collect ideas for a future nationwide antismoking program.

In his testimony, Dr. Brian Danaher, director of the Stanford program, called attention to studies associating maternal smoking during pregnancy with reduced birth weight and increased chance of infant mortality.

"Simply, the greater the number of cigarettes smoked, the more significant the infant weight reduction," he said.

"Smoking has been shown to produce a clear and lethal byproduct when it occurs during pregnancy. . .the transmission of toxic components to the fetus, a disturbance of vitamin metabolism, and possibly reducing oxygen available to the fetus."

Research literature, he said, shows that pregnant women who are able to stop smoking in their first trimester (before the fourth month) have no more risk to their child than if they never smoked before.

In the Stanford program, women will be scheduled to begin treatment preferably before their fourth month of pregnancy. Groups of eight to 12 women will participate in discussion sessions to learn skills to stop smoking. The treatment will last six weeks. Each participant will return for follow-up maintenance sessions after the birth of her child.

The program brings together several behavior modification procedures used in other smoking cessation classes. This will be the first time in this country that the comprehensive program has been offered to pregnant women smokers, according to Danaher.

The treatment consists of initially getting the participant to stop smoking by increasing her sensitivity to unpleasant aspects of the habit.

Once cessation is achieved, says Danaher, participants will focus on developing self-control skills to deal with lingering smoking urges. These skills include deep muscular relaxation, used as a substitute for smoking and as a means of coping with stress.

Participants will keep diaries and learn how to change their daily routines to reduce their smoking urges. Other strategies are included in a workbook and audio cassette tapes for home use.

Danaher was optimistic that pregnant women could be successful in stopping smoking, since "they are already prone to making substantial everyday changes in their habits, and there is an increased concern with matters of health."

He called attention to the steadily increasing numbers of women smokers of childbearing age. American Cancer Society figures show that the percentage of heavy smokers (at least one pack per day) among young women under 35 increased from 20 to 22 percent since 1969. Teenage girl smokers increased from 22 to 25 percent, with heavy smokers up from 2.2 to 10.8 percent. "This increase in heavy smoking in teenage girls who may bear children seems particularly ominous," he said.

Danaher noted that expectant mothers interested in participating in the Stanford study may call him at 497-0323.

END ADVANCE FOR RELEASE AFTER 11 A.M. TUESDAY, MARCH 22, IN CONJUNCTION WITH DR. DANAHER'S TESTIMONY.

STANFORD--Dr. Terrence F. Blaschke of Stanford University has been named recipient of the 1977 Burroughs Wellcome Scholar Award in Clinical Pharmacology.

The $175,000 award for five years from The Burroughs Wellcome Fund to Dr. Blaschke and the Stanford University School of Medicine was announced by Dr. George Hitchings, president of the Fund, and Dr. Clayton Rich, vice-president for medical affairs and dean of the school.

The award, one of two given by the Fund for 1977, will support teaching and research in the Division of Clinical Pharmacology at Stanford. The other recipient of a clinical pharmacology award is Dr. Russell L. Miller of Howard University College of Medicine.

The Fund, headquartered at Research Triangle Park in North Carolina, is a nonprofit organization established by Burroughs Wellcome & Co., pharmaceutical manufacturer. The Fund has distributed more than $6 million since 1959 for the advancement of medical knowledge, research, and other scientific and scholarly purposes.

Dr. Blaschke, a 34-year-old assistant professor of medicine, is the second Stanford faculty member to receive the scholar award. The first was Dr. Stanley N. Cohen, professor of medicine, who founded the Division of Clinical Pharmacology.

Dr. Blaschke is a graduate of the University of Denver, and received his medical degree from Columbia University College of Physicians and Surgeons in 1968. He received residency training in internal medicine at UCLA Center for the Health Sciences in Los Angeles, and has served as clinical associate in the metabolism branch of the National Cancer Institute in Bethesda, Maryland.

From 1972 through 1974 he was an NIH postdoctoral trainee in the division of clinical pharmacology at the University of California Medical Center in San Francisco.

At Stanford, Dr. Blaschke has been investigating the mechanisms and significance of certain drug interactions, and the effect of liver diseases on the disposition of drugs eliminated by the liver.

In addition, he supervises Stanford medical students electing clerkships in clinical pharmacology, and teaches medical students and postdoctoral fellows.

The goals of the Division of Clinical Pharmacology over the next five years is to stregthen its involvement in the areas of patient consultation and medical student and house staff education, and to increase its role in the training of physicians for careers in clinical pharmacology, according to Dr. Cohen, head of the division. ###

FOR IMMEDIATE RELEASE

STANFORD –

Dr. Emile F. Holman, a professor of surgery emeritus whose distinguished career at Stanford University had spanned nearly 50 years, died Saturday, March 19, at 86.

Dr. Holman, a San Francisco resident, passed away at Children's Hospital.

The son of a minister, Dr. Holman received his A.B. from Stanford in 1911. His academic career was full of promise and his potentialities were recognized by David Starr Jordan, then Stanford president, who selected him as his secretary.

He accompanied President Jordan on his peace mission through the Balkans in 1914, and at the end of that year he became a Rhodes Scholar and studied at Oxford University until 1917.

At Oxford, Dr. Holman came under the instruction of some of the greatest men of medicine of the day, including such notables as Charles Sherrington and Sir William Osler.

Osler wrote in a letter recommending Dr. Holman for admission to the Johns Hopkins Medical School: "He is an A-1 student and will be a great credit to the School. I don't think there is any doubt that he will have done enough work to warrant admission to the fourth year."

Dr. Holman graduated from the Johns Hopkins Medical School in 1918. He then became assistant in surgery in the Surgical Hunterian Laboratory, the research laboratory of the noted physician, W.S. Halsted.

By 1922, when Halsted died, Dr. Holman knew he wanted to enter academic medicine. He took additional training at The Peter Bent Brigham Hospital in Boston under Dr. Harvey Cushing, then worked for a period with Dr. Elliot Cutler at Western Reserve University in Cleveland.

In 1925 he returned to Stanford as associate professor to become professor of surgery and chairman of the department in 1926, a position he held until his retirement from the faculty in 1955.

Dr. Holman liked to explore novel ideas in the laboratory, and he was known as the predominant authority on arteriovenous fistulas, research which won him the coveted Gross prize in surgery in 1930. In 1972 he was honored by the International Congress of the Transplantation Society for his pioneering work in the field of skin grafting and graft rejection.

In addition, he contributed to the development of the surgical treatment of "blue babies" and was the first to perform the delicate operation on the West Coast.

In 1952 Dr. Holman received the Rudolph Matas Award in Vascular Surgery, generally regarded as the world's highest recognition for surgery of the heart and blood vessels. He authored three books, contributed to others, and published 187 articles in medical journals.

At Stanford, Dr. Holman was honored by having an endowed professorship named after him. The Emile Holman Professorship of Surgery was established in 1972 by a bequest from the estate of Deane and Louise Dart Mitchell, lifelong friends of Dr. Holman.

Dr. Holman is survived by his wife, Dr. Ann Peril Purdy, clinical professor of pediatrics emeritus at Stanford; three sons, David, Halsted and Shawn Holman, and nine grandchildren.

In accordance with his wishes, there will be no funeral service. His ashes will be scattered at sea.

The family has requested the memorial donations be sent to the Department of Surgery, Stanford University School of Medicine.

STANFORD--Guidance counselors from 38 high schools and community colleges on the San Francisco Peninsula are expected to attend Stanford University Medical Center's first Health Careers Day Friday, March 25.

The day-long program in the new Sherman Fairchild Auditorium will include presentations by medical-health professionals at the medical center and information booths on health careers.

According to Larry Esquibel, associate director for medical center personnel, the event is designed to inform counselors of the most recent developments in the health careers field and to provide them with the opportunity to meet professionals working in the field. This interchange, Esquibel noted, will help counselors in their advice and assistance to young people planning health careers.

The addresses will be given by Dr. Michael Eliastam, director of Stanford Hospital's Emergency Services, who will speak on "Career Options in Medicine," and Wendy Squyres, manager of education and development in medical center personnel, whose talk is on "The Role of the Educator in Career Counseling."

FOR IMMEDIATE RELEASE
STANFORD –

Following is a commentary by Dr Arthur Kornberg, Nobel Laureate and professor of biochemistry at the Stanford University School of Medicine. He discusses why society's long-term commitment to the advancement of scientific knowledge must be free of political partisanship. The article is adapted from the winter 1977 issue of *Stanford M.D* magazine.

THE FRAGILITY OF BASIC RESEARCH SUPPORT
by Arthur Kornberg, M.D.

There has been in our lifetime a revolution in biology! Do we appreciate this revolutionary change and do we respond to it? Certainly laymen don't They don't understand biology, and they are justifiably skeptical, having heard claims of revolutionary changes in everything from deodorants to space travel.

Yet today we write precise chemical formulae for the genetic substance, and we synthesize and manipulate it in our laboratories We understand in simple biochemical terms how the gene is expressed and reproduced. We do see the cell in some of its molecular detail in the electron microscope, and we see it even down to atomic dimensions by spectroscopy These techniques and insights have brought a confluence of genetics and chemistry, anatomy and physiology Understanding the structure and function of the cell and organism is becoming a single, unified scientific enterprise with a coherent logic.

Realistically I know that only a tiny fraction of our fellow citizens share these visions of nature and the passion to enlarge them There is, however, an area of interest, closely related to science, which we do share with informed citizens It is the concern that we get a proper product for the money spent on health care in this country. We spend 120 billion dollars on health care annually, but we are not getting our money's worth. We waste much of what we spend on the prevention and treatment of cancer, heart disease, diabetes, and mental illness because the available knowledge and procedures are so primitive and ineffective. The only sure way to improve these procedures is to understand the cell and organism well enough to deal rationally with pathologic changes. No sensible person will consign an ailing watch or car to mechanics who are ignorant about their working parts. It stands to reason we cannot maintain or repair a human machine we don't understand.

How then can we inform and persuade people of the importance of the advances in biology and the opportunities they present for our future welfare? It has been and will remain an exceedingly difficult and frustrating problem. One approach is to educate the public about science. We can show that the pathway to practical benefits started from fundamental science and that the pathway was circuitous and took many years to traverse. We can point out that the key discoveries which made X rays, penicillin, and polio vaccine possible were not related to research on disease. These medical miracles came from the curiosity of physicists, bacteriologists, biochemists, and cell biologists about basic scientific questions unrelated to medicine. Once the insights and techniques were discovered, the applications to medicine were rapid and dramatic. Conversely, crash and costly programs directed to the curing of diseases have invariably failed when the basic knowledge needed for application was lacking.

(more)

When I realize the long and extensive exposure these Senators have had to good advice about the need for long-term support for basic research, I am convinced of the futility of the approaches we have taken to educate the public and our legislators.

People and politicians see the current problems and want quick solutions. Despite all that the history of medical science has taught us, there is an irresistible urge to gamble on a quick payoff. It makes little sense to legislators to fund something as esoteric as my own studies of the replicative life cycle of bacteriophage ØX174 in E. coli when cancer ravages their relatives and constituents. They don't know that such studies inform us of the cellular chemistry of DNA, knowledge essential for understanding and preventing cancer.

What strategies can we adopt to assure the vigorous and sustained support for the scientific effort needed to advance basic biology and its applications to clinical medicine? This problem has vast social, economic, political, and scientific complexities. Frankly, it is quite beyond the abilities, capacities, and inclinations we have as scientists. Sporadic appeals to the public and Congress may have averted a few disasters, but they are ineffectual in the long run. What would work is a law committing the federal government to invest a fixed percentage of the gross health product in the research needed to improve it. For example, spending 5 or 6% of the health industry dollar for research to make it more technologically reliable would seem to be a prudent and conservative investment. An investment of this size would call for an immediate expansion of biomedical training and research rather than the retrenchment which has taken place and is being planned for the future.

Few of us can or wish to engage in the political process needed for such a long-term commitment for basic and applied biomedical research. Yet there is something we can all do. We can show in our daily lives that we believe science is important. The majority of biomedical scientists, although highly competent and fully deserving of support, do not display the conviction, the absolute dedication—in short, the passion—that the advancement of knowledge is the most important facet of their professional lives. Without such conviction, their pleas for support of science are dissonant and muted. Their shiftlessness is transparent.

I have elaborated on some of the elementary guidelines for a rational scientific enterprise that I used to think could be taken for granted. Unfortunately, we cannot take these truths to be self-evident.

We must keep informing others, but even more important, reinforcing our own convictions that you can't teach what you don't know, you can't solve problems by wild guessing. Understanding nature in the broadest and most basic terms is the most economical and conservative way, the only way, to solve the practical problems of maintaining health and curing disease.

I am convinced that the approaches we have used to persuade our fellow citizens and legislators to support biomedical science, research, and training at a rigorous and basic level will not work. We need a long-term commitment free of political partisanship, but I am unable to suggest effective political mechanisms for scientists to achieve this by themselves. It will taken full-time, sustained, professional political help and guidance to do it. What we as scientists *can* do for ourselves is to practice good science and give it our unequivocal devotion.

—30—

Unfortunately, educating the citizen and the legislator of the importance of basic research has never been a confident and sustained undertaking; partial efforts in this direction have generally failed. The massive federal support of basic research in the postwar era was hidden under the cloak of defense agencies and the numerous categorical disease institutes of the National Institutes of Health (NIH). The bulging muscle of this basic research effort was skillfully disguised by expert tailoring by administrators of these government departments. It was recognized and winked at by a few dedicated and influential congressmen and then sold by them to their colleagues.

But inevitably these disguises became too worn and obvious. I recall an exchange between the late Congressman John L. Fogarty, the patron saint of the NIH and of medical research in the House (just as Lister Hill was in the Senate), and Dr. Fred Stone, then director of the National Institute of General Medical Sciences. It took place in 1966 shortly before Fogarty died; it was at a hearing on NIH appropriations before the subcommittee which he chaired. Fogarty asked Stone, and I quote from the Congressional Record:

Mr. F: "What is the difference between DNA and RNA? I don't understand either of them although they have been explained to me four or five times now."

Dr. Stone: "I share some of your confusion, sir. DNA is Deoxyribonucleic Acid. The other is Ribonucleic Acid. The difference between the two lies in a difference in the ribose sugar."

Mr. F: "I don't know any more than when you started."

Forgarty went on in the same hearings to complain that scientists were coming up with more and more interesting questions but not enough answers. He was concerned that there might be a lag in the application of basic knowledge to disease.

Also in 1966 President Lyndon Johnson expressed his concern that basic research was not paying off. He said, "Presidents need to show more interest in what the specific results of research are in their lifetime and *in their administration*. A great deal of basic research has been done but I think the time has come to zero in on the targets by trying to get our knowledge fully applied. We must make sure that no life-saving discovery is locked up in the laboratory."

One of the Johnson legacies tha Richard Nixon eagerly accepted was his impatience with basic research. His administration called for crusades to vanquish cancer and heart disease without regard for the fact that we lacked the weapons to conduct such major wars at that time.

During these past 10 years we heard a barrage of increasng ferocity against basic research. Turn research to the service of man. Develop strategies to cure disease. Do health-oriented or disease-oriented research. Give us answers, not questions.

The latest volley was fired last summer by Senators Edward Kennedy and Richard Schweiker. In their review and examination of public policy in biomedical research they began by sharply questioning the President's Biomedical Research Panel and the Panel's report. Kennedy complained that medical research seemed to be dedicated to uncovering new knowledge—for science's sake (for the amusement of the scientist)—not for the conquest of specific diseases or development of new technologies. He was fed up with giving the NIH money to *understand* disease; it was time they concentrated on their mandate: namely, the prevention, diagnosis, and treatment of disease.

Schweiker was even more specific. With a particular zeal for diabetes, he demanded an all-out effort to develop an artificial pancreas for each of the nation's millions of diabetics. The device is an implanted reservoir designed to deliver insulin automatically. I presume it is supposed to respond to computer directions based on constant analysis of blood glucose and insulin levels. Do we know enough about diabetes to warrant such a crash program at a staggering cost? Even more serious is the danger of such an implanted device. Would you today accept an implant with a multilethal dose of insulin? I wouldn't.

STANFORD--A new textbook on infectious diseases that can affect the fetus and newborn infant has been compiled by Dr. Jack S. Remington, M.D., professor of medicine in the division of infectious diseases at Stanford University School of Medicine. His co-author is Dr. Jerome O. Klein, associate professor of pediatrics at Harvard Medical School.

The book, Infectious Diseases of the Fetus and Newborn Infant (W.B. Saunders and Company, Philadelphia, 1976. 1121 pages, $45.00), is a summary of major advances in biology and medicine over the past two decades in infectious diseases which occur in fetus' and newborns in the United States and Europe.

It is directed to medical students, practicing physicians, microbiologists and other health care workers, and provides a complete, critical and contemporary review of existing information on infectious diseases that can be acquired in utero, during delivery and in the early months of life.

The book's twenty chapters were written by people who are recognized authorities in their fields. Each has made significant contributions to the understanding of infection in the fetus and neonate.

Included are chapters on immunology, rubella, neonatal diarrhea, herpes simplex, syphilis, hepatitis, fungal and bacterial infections and the pharmacology of antibacterial agents.

Dr. Remington is chief of the division of allergy, immunology and infectious diseases at the Palo Alto Medical Research Institute. Dr. Klein is associate director of the Department of Pediatrics at Boston City Hospital.

STANFORD--Dr. William P. Creger, associate dean for student affairs, has resigned from his part-time administrative post.

Dr. Creger will continue as professor of medicine (hematology), on the Stanford medical faculty.

As associate dean, which was in addition to his demanding clinical responsibilities and teaching schedule, Dr. Creger has advised students about their clinical training, especially their internship plans since 1968.

Dr. Creger once described his administrative role as a "matchmaking service which collates the characteristics of those medical students who are about to graduate, and is sent to hospitals which are about to select next year's residents."

"There's little that regulates this function, not a handbook, not a certifying specialty board, and it may not be an analyzable function," he wrote.

Dr. Creger will be on sabbatical leave in Europe for the next three months.

No successor for the part-time administrative post has yet been named, according to the Dean's Office.

City Editors: This sidebar supplements the main story of the dedication ceremonies mailed today.

STANFORD--Research ranging from studies of the molecular basis of vision to genetic controls of the immune system will be among projects carried out in the Sherman Fairchild Science Building of the Stanford University School of Medicine.

The multimillion dollar center, dedicated Saturday, March 12, consists of a four-story science building and a 386-seat auditorium located adjacent to the medical school.

The research which will be housed in the building was discussed at a morning symposium by the scientists who will direct the work, beginning with Dr. Lubert Stryer, chairman of the Department of Structural Biology.

He described his studies in the mechanism of visual excitation in the rod cells of the retina, which convert light into nerve impulses.

There are some 100 million rods in the human retina, Stryer explained, which are responsible for black and white vision. Each rod contains a stack of about 1,000 discs which contain molecules called rhodopsin to absorb light coming into the eye.

When light strikes a rhodopsin molecule, it changes shape and sends a signal to the outer envelop of the cell. Most remarkable, said Stryer, is that rods can be excited by receiving a single quantum of light. This initial acknowledgment that light has been seen has been measured at faster than one millionth of a second.

Stryer said he is trying to learn the precise function of the rhodopsin molecule to determine how it recognizes light and transmits this information to the cell. He is also studying the structure of the molecule because its physiology is inevitably connected to its architecture.

Stryer, like other scientists who will work in the Fairchild building, feels it is important to understand what happens at this stage of the visual process in order to look further.

Nobel Laureate Arthur Kornberg, sitting in the audience, suggested it would be a good idea to study rhodopsin molecules in simpler organisms than animals.

Such molecules are found in the membranes of brine bacteria in the salt ponds of San Francisco Bay, he said. "It is such basic, apparently irrelevant, studies that will ultimately be of great benefit for human diseases of vision and cell growth."

-more-

Another scientist, Dr. Eric Shooter, spoke about work involving nerve growth factor. Shooter, who heads the Department of Neurobiology, and his colleagues, have isolated and recently crystallized this protein that affects the development, differentiation, and maintenance of certain nerve cells.

Shooter said nerve growth factor is necessary for the development of nerve cells.

He said there are probably a number of diseases of the nervous system that have a direct connection to nerve growth factor.

Work on the genetic controls of the immune system was described by Dr. Hugh McDevitt, head of the division of immunology. His group has discovered that the genes controlling the ability of the body to respond to infection are clustered together on one chromosome in the mouse and are closely linked to the genes responsible for destroying foreign grafts.

"Existence of these genes, called immune response genes, has opened up a whole new approach to certain diseases," said McDevitt. Studies with animals have indicated that different transplantation antigens are associated with different diseases.

"Similar associations in humans could mean that immune response genes determine susceptibility or resistance to certain diseases," he explained.

In recent years, McDevitt said, investigators have found striking associations between a particular transplant antigen and disorders thought to be the result of an abnormal immune response. These include ragweed hayfever, several autoimmune diseases and arthritis, multiple sclerosis, psoriasis and cancers such as acute lymphocytic leukemia in children and Hodgkin's disease.

A link between disease susceptibility and transplantation antigens can help identify persons who are prone to certain diseases because of their genetic makeup, he said.

The Fairchild Center was built with the support of an $8.25 million gift from the Sherman Fairchild Foundation of Greenwich, Connecticut, named for the founder of Fairchild Camera and Instrument Corporation and Fairchild Industries.

Additional funds came from Mrs. George A. Winzer of La Jolla, California, a longtime benefactor of the medical school. The Max C. Fleischmann Foundation of Reno, Nevada, recently provided a $1.5 million grant for completion of the top floor of the science building.

STANFORD--Basic research, the lifeline of medicine, is now threatened by strong social, economic and political pressures, Dr. Arthur Kornberg, Stanford's Nobel prize winning biochemist, said Saturday, March 12.

"These pressures come from within institutions as well as from outside," he said. "They discourage financial support of basic research and question its importance.

"They drive scientists to undertake excessively complex problems in a gamble for quick payoffs. They make scientists into enterpreneurs and administrators."

Kornberg, speaking at the dedication of the Sherman Fairchild Science Building at the Stanford University School of Medicine, said "it is just such times that test our temper."

The scientist or practitioner of medicine, said Kornberg, must adhere to the fundamental discipline of science by asking discrete and well defined questions and persist at it doggedly year in and year out.

"It is out of these small, but sustained contributions to knowledge that we build the grand edifices of nature," he said.

One of the problems, Kornberg said, has been the impatience of the politicians with basic research. They have called for crusades to vanquish cancer and heart disease without regard to the fact that we lacked the weapons to conduct such major wars.

More recently, he added, "we have a guru in Sacramento who preaches an ethic of lowered expectations, a philosophy that would discourage us from bold and innovative explorations of the frontiers of knowledge.

"And in our California State Health Department, the governor employs a full-time bioethicist whose current occupation is fanning the hysteria developing about recombinant DNA research."

Kornberg stressed the gene-splicing technique "is not a health hazard or a weapon. Its use and development bear no resemblance to that of nuclear fission and producing bombs."

"Its potential to become a menace is exceedingly remote," he said. "Compared to existing menaces, about which we need to worry--overpopulation, over and underconsumption of food and energy, carcinogens, nuclear weapons--I would not list recombinant DNA among the top 25 or even the next 100."

Kornberg said research is essential for advances in medicine. "Unless it advances, medicine regresses. Medicine regresses because the status quo is continually challenged with new problems--novel toxins, resistant organisms, regressive attitudes, such as astrology, food fads and other witchcraft.

-more-

"There will be no solutions to major disease problems for which we lack basic knowledge, short of acquiring that knowledge."

Another speaker, David Hamburg, president of the Institute of Medicine of the National Academy of Sciences, said that excellence in research is no longer in question.

"The U.S. has the greatest health research establishment in the world," said Hamburg. "But there are broad concerns about the relationships of this excellence to health."

There is a need for research to evaluate effectiveness of many therapies, and to face the dilemma of the relationship of personal behavior to health, he said.

American medicine, said Hamburg, has also a moral commitment to do something about the health problems of developing countries where infectious diseases heightened by malnutrition are still rampant.

About 400 persons attended the dedication of the Sherman Fairchild Science Building. The departments of structural biology (formerly anatomy) and neurobiology are housed in the four-story multimillion dollar building, located adjacent to the medical school.

The building, which is constructed around an atrium, contains laboratories, conference rooms, and administrative offices. The Fairchild auditorium has been built adjoining the science building. This 386-seat facility will be used for medical school classes and lectures as well as events to which the public is invited.

The Fairchild Center is the result of an $8.25 million gift from the Sherman Fairchild Foundation of Greenwich, Connecticut named for the founder of Fairchild Camera and Instrument Corporation and Fairchild Industries.

Additional funds came from Mrs. George A. Winzer of La Jolla, California, a longtime benefactor of the medical school. The Max C. Fleischmann Foundation of Reno, Nevada, recently provided a $1.5 million grant for completion of the top floor of the science building.

Participants at the ceremonies included Walter F. Burke, president of the Sherman Fairchild Foundation; Dr. Peter S. Bing, president of the Stanford board of trustees; President Richard W. Lyman, and Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine.

The new building and auditorium were designed by the San Francisco architectural firm of Stone, Marraccini and Patterson. Turner Construction Company of San Francisco was the general contractor. Landscaping was done by A. and J. Shooter and Associates of Mountain View, California.

STANFORD--If Dr. Paul D. Thompson wants to be dressed for work he has to literally run for his clothes each day.

Puzzled? Actually, it's a well-devised plan by Thompson to get part of his daily exercise into an otherwise jammed work schedule.

Thompson, a fellow in the Division of Cardiology at Stanford University Medical School and a staff member of the Stanford Heart Disease Prevention Program, purposely keeps his clothes in his office so he can run to work from his home in Escondido Village on campus. At night he reverses the process, often taking a circuitous route on campus in order to get in more exercise.

"This system works for me," Thompson noted. "Because of my schedule I don't always get to run when I want. But, when I do, I've never had a run where I didn't feel good at the end of it."

Probably because of the nature of his work, Thompson strongly advocates the "benefits" of exercise and he wishes more people would take the time to do it.

"I'm committed to the prevention of heart disease and I believe it's important to reduce the 'risk factors' of heart disease, such as smoking, high cholesterol counts, stress and excess body weights. The 'strength' of exercise is that it helps reduce some of these risk factors."

Thompson estimates that between 40 and 60 percent of those who have initial episodes of cardiovascular disease will die within one year from it.

Aside from the medical benefits of exercise, Thompson says he runs because he enjoys it.

"I've been running since I was about 14 and I ran in high school and college. I continued to run after I was out of school and I guess you could say I've incorporated it into my lifestyle."

Thompson was captain of cross country teams in high school and college and was named athlete of the year at Tufts University and in eastern Massachusetts. He received both his Bachelor of Science degree and his M.D. from Tufts (Medford, Mass.)

Since college, Thompson has also participated in various races, including the Dipsea Race last summer in Marin County, the Boston Marathon and the 26-mile Paul Masson Marathon in Saratoga last January, which he won. Thompson says he hasn't decided yet whether he will enter the Annual Bay-to-Breakers Race sponsored by the San Francisco Examiner on May 15.

However, although he enjoys the running competition, Thompson believes it is more important that the masses take up regular exercise.

"Even though I know I am not good enough to win in the Olympics I wish I could do so," he said, "because it would provide a great opportunity to publicize the value of fitness for every individual."

STANFORD--Stanford University Hospital will have a new emergency room on Tuesday, March 15.

The switch to the expanded facilities in the new wing of the hospital will take place at 12:01 a.m. Tuesday, according to Dr. Michael Eliastam, director of the emergency department.

The new emergency room will be located on the first floor of the new wing. The unit is located just off Quarry Road, near the access road to the former emergency room.

Direction signs have been posted inside the hospital and in the surrounding area, and ambulance companies have been notified of the change of location.

Patients arriving anytime Monday before midnight will be treated in the existing facilities. Patients arriving after midnight will be directed to the new location. Medical staff will continue to provide care in the old area as long as patients remain there.

The new facility will provide more space as well as improved equipment, according to Eliastam.

The new unit will be about twice the size of the old, with 18 treatment rooms and a special acute resuscitation room featuring modern wall-mounted equipment panels. One area has been designated a family room, where families of patients may confer with doctors privately.

There are expanded observation areas, a waiting room, nurses lounge, X ray facilities, and a special room for psychiatric care.

Dr. Eliastam notes that the new unit will be closer to the heliport, to the intensive care unit, and to blood bank and radiological services.

The emergency room represents the first patient care activity to begin in the new hospital wing. Surgical pathology and blood coagulation and transfusion laboratories were moved into the wing last December. In the future, the building will also include 25 intensive care beds, plus needed support facilities, including radiology, cardiology, surgical and postanesthesia recovery areas.

The former emergency room on the hospital's ground floor will be renovated to accommodate a new oncology day care center for treatment of cancer patients.

FOR IMMEDIATE RELEASE

STANFORD –

"Human Rights and Science in the Soviet Union" will be the topic of a public lecture by Soviet biologist Edward Trifonov at noon Monday, March 14, in Room M114 of the Stanford University School of Medicine.

Dr. Trifonov was a member of the Biological Department of the Kurchatov Institute of Atomic Energy in the Soviet Union. He recently joined the staff of the Weizmann Institute of Science in Rehovot, Israel.

His visit to the United States is sponsored by the Committee for Concerned Scientists, New York. His talk at Stanford is being sponsored by the Department of Biochemistry.

The Soviet Jewish scientist credits his release from the Soviet Union to an international letter-writing campaign by fellow scientists.

According to a press statement from the Weizmann Institute, Dr. Arthur Kornberg, Nobel laureate in medicine and professor of biochemistry at Stanford, was among the many who addressed letters to Prof. Anatoly Alexandrov, president of the Soviet Academy of Sciences.

Dr. Kornberg, a member of the Institute's board of governors, wrote, according to the press release, "I regard these harsh restraints on Soviet scientists as a serious restriction on the whole international community of scientists. . . .It is only in the free movement of creative people between our various cultures and societies that we can hope to achieve peace, understanding, and prosperity."

Editors: This story is released jointly by the Stanford Primary Care Associate Program and the UC-Davis Family Nurse Practitioner Program. Contact person at UC-Davis is Nancy Johnson, 916: 453-3550.

STANFORD--A new program to train both physician's assistants (PAs) and nurse practitioners with the same curriculum is now underway in two California communities.

The cooperative venture combines the resources of both Stanford University Medical Center's Primary Care Associate Program and the University of California at Davis's Family Nurse Practitioner Program. The Robert Wood Johnson Foundation has provided three-year support for the project totaling $198,573.

Seventeen physician's assistants and nurse practitioners in Redding and nine in Stockton are now undergoing the first joint clinical training.

Virginia Fowkes, project director at Stanford, notes that the functions of the two practitioners are quite similar, despite the different backgrounds and titles.

"There is substantial evidence that the two programs provide similar educational experiences and produce graduates who practice in comparable settings with similar responsibilities," she says.

Both family nurse practitioners and PAs work with physicians delivering a variety of services, including history-taking, physical examination, basic laboratory techniques, minor diagnostic and therapeutic procedures, and patient counseling and education.

The aim of the Stanford PA program has been to recruit from and train practitioners in health care shortage areas with the expectation that graduates will remain in these communities for practice.

Preclinical course work is provided at community colleges in Eureka, Redding, Modesto, Salinas and Bakersfield as well as at Foothill College in Los Altos.

The Davis Family Nurse Practitioner Program has similar goals and is also decentralized with a network of training programs established throughout northern and central California. Mary O'Hara-Devereaux of UC-Davis is codirector of the new project.

-more-

222--Primary Care Associate Program

"We think this will be a more cost-effective approach to training," says Virginia Fowkes. "We feel that we are in a unique position to combine resources and to put aside the political and emotional differences traditionally encountered among those two professions."

In awarding the grant, the Robert Wood Johnson Foundation noted that "the number of nurse practitioner and PA training programs has proliferated in recent years, with each being conducted under a separate curricula. This has led to a wasteful duplication of physician teaching time and clinical training sites."

Faculty for the project includes Stanford and UC-Davis physicians, family practice residents in the communities, family physicians on the staff of the universities, and graduates of both programs.

In the Stockton program, students are located in areas within a two-hour traveling distance of Stockton. They gather once each week for classes at San Joaquin General Hospital, and during the remainder of the week work with individual family physicians in the rural areas who serve as preceptors.

Because of the greater distances involved near Redding, students there meet once a month for three days on a weekend for classes held at Shasta General Hospital. In addition, smaller interim teaching seminars are held once a month in the Redding and Eureka areas.

In addition to the Robert Wood Johnson grant, the project is supported by Song-Brown funds administered by the California Health Manpower Policy Commission and the Bureau of Health Manpower, Department of Health, Education and Welfare.

STANFORD –

Lane Medical Library at Stanford now has a collection of materials on recombinant DNA which is open to the general public, Vice-Provost William F. Massy reported to the Faculty Senate last week.

The library is open from 8 a.m. to midnight Monday through Thursday, from 8 a.m. to 10 p.m. Friday and Saturday, and from 10 a.m. to 10 p.m. Sunday.

Massy said the administrative panel on recombinant DNA plans to have every fourth meeting open to the general public. Times and places will be announced later. The panel's minutes are available to the public at Lane Library and at Meyer Undergraduate Library, which has a smaller collection of DNA reading materials.

At a public hearing last month, several persons questioned the pending Stanford-UC application for a patent on certain processes in this field. Massy noted that Stanford has made "an administrative decision" to require that any licensees follow the National Institute Health guidelines for this field, together with any additional constraints established by the University.

(In a letter to State Assemblyman Barry Keene, Jan. 27, Stanford Vice-President Robert Rosenzweig said: "As it became clear that recombinant DNA was a controversial subject, it became evident, too, that an attempt to seek a patent would be caught up in that controversy.

("Since members of the Stanford faculty were and are prominently involved in the debate over the conditions under which the research should proceed, we had to face the possibility that their participation would be compromised by charges—no matter how unwarranted they might be—of a conflict of interest.

("Therefore, we returned to NIH with a request that they consider again the legitimacy of our moving to seek patent protection. After extensive deliberation and wide consultation, NIH reaffirmed its approval. The present situation is that we are proceeding with our patent application. We have put it abeyance, however, any plans to move to commercial licensing of the invention.")

Massy told the Faculty Senate that Prof. Stanley Cohen of the Medical School already has assigned his share of any patent income to the School. Massy said he saw no conflict of interest in Cohen's membership on the panel, whose composition is in accord with government guidelines.

At present, Massy noted, the panel's top priority is consolidating monitoring policies and practices, using the NIH guidelines and any additional directives the panel itself may establish.

University health and safety monitors have "full responsibility" to see that policies and procedures are carried out on a continuing basis, he said. This includes access to the laboratories and all the information that the principal investigator or anyone else can provide.

In response to questions, Massy said monitoring of recombinant DNA is probably harder than that for radiological hazards.

Several types of monitoring may be needed. One would be "very sophisticated" and "very difficult," checking to see whether anything has escaped into the atmosphere of the laboratory. While this "probably is impossible to do on a wide scale. . .it can be done specifically" in small areas, he said.

Another, simpler type of monitoring has to do "with people's adherence to procedures, whether in fact work is being done in safety cabinets. . .whether proper safeguards are being taken." This can be enforced through random visits to laboratories, among other methods.

Should it prove necessary, the monitors have the authority to halt work on a project or to close an entire laboratory.

Massy said his own analysis of presently available data indicates that "the probabilities of difficulty are very low indeed. . . However, it is important that no one person goes off in a corner and makes that judgment" alone.

He noted that the administrative panel is "a Stanford entity. . .to help us exercise our institutional responsibility, which we take very seriously." While its membership includes individuals from surrounding communities who "provide an important view," they are not "representative. . .in a political sense."

The panel is headed by Prof. Allen Campbell, biology.

STANFORD--Cancer will be the topic of a series of four lectures which will begin at 7:30 p.m., Wednesday, May 4, in the Sherman Fairchild Auditorium of Stanford University Medical Center.

The lectures are open to the public.

The first lecture, "What Causes Cancer?" will be delivered by Dr. Henry Kaplan, Maureen Lyles D'Ambrogio professor of radiology and director of Stanford's Cancer Biology Research Laboratory. Dr. Kaplan is an internationally-known pioneer in cancer research, especially in the fields of human lymphomas and leukemias.

Dr. Kaplan will be introduced May 4 by Dr. Joshua Lederberg, chairman of the department of genetics. Lederberg initiated the Progress in Medicine Lecture Series in 1966 to provide an opportunity for leaders in academic medicine at Stanford to share information, insights and perspective with members of the community.

The three other lectures scheduled in the cancer series are as follows:

May 11: "New Ways to Diagnose Cancer: The Impact of Technology," by Dr. I. Ross McDougall, associate professor of radiology, division of nuclear medicine, and Dr. Leslie M. Zatz, professor of radiology, division of diagnostic radiology and chief of radiology at the Palo Alto Veterans Administration Hospital.

May 23: "Treatments for Cancer: New Therapies," by Dr. Saul A. Rosenberg, professor of medicine and radiology and chief of the division of oncology, and Dr. Sarah S. Donaldson, assistant professor of radiology, division of radiation therapy.

June 1: "Cancer and the Individual: The Effect on Patient and Family," a panel discussion moderated by Dr. Don R. Goffinet, assistant professor of radiology, division of radiation therapy. Members of the panel are: Suzanne S. Miller, R.N., clinical oncology nurse coordinator; Dr. Frank E. Stockdale, associate professor of medicine, division of oncology; Dr. Frederic J. VanRheenen, clinical assistant professor of psychiatry; Isabel Walker, R.N., M.S.W., clinical social worker, division of oncology; and Ernle W.D. Young, chaplain to the Stanford University Medical Center and instructor of medical ethics.

STANFORD –

A charge of unfair labor practices against Stanford University in connection with an employee survey held recently at Stanford Medical Center has been dismissed by the National Labor Relations Board (NLRB) in San Francisco.

The charge had been filed with the NLRB by United Stanford Employees (USE).

In a letter to USE president Anne Schlagenhaft, NLRB Regional Director Natalie P. Allen said the Board had decided not to issue a complaint against the University in the case. Allen explained that the NLRB had found "no reason" to believe the National Labor Relations Act had been violated by the University, and that Stanford "did not interfere, restrain, or coerce its employees by conducting the employee opinion survey."

USE will have until May 2 to appeal the decision, in writing, to the NLRB's General Counsel in Washington, D.C.

USE had charged that the survey, which was conducted in February at Stanford Hospital and Clinics and Stanford Medical School, was a possible violation of the National Labor Relations Act by attempting to "supplant the union."

Although the survey forms were answered anonymously, USE complained that some worker identities could be determined because of the demographic nature of the questions.

According to Ron Twomey, Medical Center director of personnel, the survey was designed to examine 16 major categories of employee opinions, ranging from job satisfaction to supervisory practices.

"It was not a scorecard or a report card, but data from employees which can be very helpful to the administration in planning for a better hospital," Twomey said.

Although the results from the Hospital survey are being analyzed by Medical Center personnel officials, information from the survey in the Hospital clinics and the Medical School are still being computerized.

USE represents about 1,350 technical maintenance and service employees on campus, including about 260 of the approximately 5,000 employees in the Medical Center.

STANFORD--Stanford University Hospital has received a one-year accreditation under the consolidated survey program of the Joint Commission on Accreditation of Hospitals (JCAH) and the California Medical Association (CMA).

JCAH-CMA surveyors inspected the hospital in January. Included on their list of recommendations identifying areas for improvement were the hospital's corporate bylaws, medical staff bylaws, service responsibilities within the medical staff, departmental meetings, medical records, and aspects of physical facilities.

In a report to the hospital, Dr. A. Walter Hoover, JCAH acting program director, noted that many of the problems cited by surveyors have been corrected.

Hoover wrote that the commission and the CMA "commends the work that you have done thus far toward achieving accreditation, but recognizes...that some specific areas deserve special attention."

Paul Hofmann, director of the hospital and clinics, said all concerns of the surveyors are now being addressed. Two receiving special attention are deficiencies due to the high utilization of the hospital and a lack of space.

He said, for example, a study of facilities is under way to determine remodeling costs for specific areas which may not comply fully with new state regulations for acute care hospitals.

Representatives for the California State Health Department also participated in the survey for licensing purposes. Their report is expected in the near future, according to Hofmann.

The purpose of the JCAH-CMA consolidated survey is to help hospitals maintain the highest quality patient care.

Surveyors spend one to three days at a hospital reviewing the medical staff's organization, the treatment of patients, and the documentation and evaluation of medical care.

The maximum accreditation a hospital can receive is two years.

SCIENCE WRITERS: Science roundup describing new developments and research in progress at Stanford University School of Medicine will be issued from time to time to encompass short items not covered in regular press releases. The items below cover developments in the neurosciences.

Photos available upon request.

STANFORD--Even though the eye is one of the finest instruments of which science has any knowledge, it is only recently that researchers have begun to unravel the secrets of vision at the molecular level.

Dr. Lubert Stryer of Stanford University School of Medicine wants to know what is the mechanism of visual excitation in the rod cells of the retina, which convert light into nerve impulses.

There are some 100 million rods in the human retina, Stryer explains, which are responsible for black and white vision. Each rod contains a stack of about 1,000 discs which contain molecules called rhodopsin to absorb light coming into the eye.

When light strikes a rhodopsin molecule, it changes shape and sends a signal to the outer envelope of the cell. Most remarkable, says Stryer, is that rods can be excited by receiving a single quantum of light. This initial acknowledgment that light has been seen was measured at faster than one millionth of a second.

Stryer says he is trying to learn the precise function of the rhodopsin molecule to determine how it recognizes light and transmits this information to the cell. He is also studying the structure of the molecule because its physiology is inevitably connected to its architecture.

Studies of vision at the molecular level, Stryer says, have been made possible by sophisticated technology which permits scientists to isolate cells and assemblies of molecules and to obtain highly magnified images of their structure.

These studies are giving scientists the most fundamental insights into the structure and function of the retinal membrane. Ultimately, Stryer hopes, they may lead to understanding of human diseases of vision and new treatments.

****

When most people think of brain surgery, they assume that the procedure is always major surgery involving a craniotomy or removal of part of the skull to reach the brain.

Neurosurgeons today, however, have devised procedures where brain surgery can be done through the nose or cheek with no incision required in the head at all.

Dr. John Hanbery, head of neurosurgery at Stanford, describes two of these procedures. One involves the removal of the pituitary gland to relieve severe pain in certain patients with cancer of the breast or prostate. This procedure is only used on patients whose cancer has spread to the point where radiation therapy and chemotherapy are no longer effective. Removal of the pituitary leads to a very dramatic relief of pain in some patients thought to be due to the manipulation of hormones, Hanbery explains.

-more-

"Surgery to remove the pituitary is done through the nose using a microscope and image intensifier. This is a relatively minor procedure which no longer involves a formal craniotomy," says Hanbery.

Tic Douloureux is another disorder now being treated without major brain surgery. The disease is an extremely painful nervous disorder involving the trigeminal nerve of the face. Some patients are treated successfully with drugs, but those who do not respond to drugs or who are bothered by side effects now have an alternative.

Instead of the major surgery used until a few years ago which involved a craniotomy to section a portion of the nerve at the base of the brain, a minor procedure is performed with the same result.

With the patient only lightly asleep, Hanbery explains, a needle electrode is inserted through the cheek. With the help of an image amplifier the electrode is passed to the base of the brain where the trigeminal nerve is located. The patient is awakened and a small electrical current is passed through the electrode, causing a tingling in certain parts of the face. When the patient feels the sensation in the part of his face affected by Tic Douloureux, he is put back to sleep and a stronger electrical charge is used to destroy the nerve.

"The patient often leaves the hospital the following day, free from pain," says Hanbery.

***

The body may produce its own tranquilizer. Dr. Avram Goldstein, professor of pharmacology at Stanford University and director of the Addiction Research Foundation in Palo Alto, has been studying the effects of endorphins, a morphine-like substance produced naturally by the body.

Endorphins have already been shown to be involved in the suppression of pain, especially during acupuncture. Acupuncture stimulates the release of endorphins which then circulate as harmones and block nerve pathways, anesthetizing parts of the body.

But Goldstein and his colleagues are also looking at how endorphins affect mood. Normal people were put into a stressful, anxiety-producing situation. Some were given a drug called naloxone which blocks the effects of endorphins. Others were given a placebo. The group receiving the placebo experienced a relaxation response once the stressful situation ended; those given naloxone remained keyed-up and anxious.

"Maybe we all carry our own dope around in our heads," Goldstein comments.

***

Severe depression may be biological in origin as well as psychological, according to a Stanford psychiatrist.

Dr. Jack Barchas, professor of psychiatry and behavioral sciences says, "We are starting to be able to determine the different biochemical systems involved in various kinds of depression. The time may come when you can go to a psychiatrist and he will do a neurochemical analysis to determine what medication you need to help with your depression in addition to psychotherapy which may still be valuable."

Different types of depression appear to be related to imbalances in various biochemical systems, he says. A low level of norepinephrine, a chemical in the brain, may be connected to one type of depression by causing altered activity among certain nerve cells which produces the symptoms of depression in the patient.

A traumatic psychological event can induce biochemical changes that result in depression. Grief is one example of this interaction. Barchas explains that unresolved grief can trigger a biochemical change which causes severe depression. This specific type of depression is both psychological and biochemical in nature and should be treated as such.

***

Today's scientists use a variety of tools, including computers, to study the brain. Dr. Leslie Dorfman, assistant professor of neurology, says, "Computer analysis is being used with increasing frequency to learn more about the electrical activities of the nervous system and also as a diagnostic aid for neurologic disease."

Dorfman's research is in multiple sclerosis which involves the deterioration of the myelin, an insulating substance over nerve cells. Without this insulation, Dorfman explains, the neurons lose some of their electrical properties--electrical signals get jumbled and the normal rate of electrical impulses is slowed.

Using the EEG (electroencephalograph) which records brain patterns and an EMG (electromyograph) which records the electrical activity in the limbs and muscles, along with the computer, Dorfman is able to measure the time it takes for a signal to pass from the nerves in the limb to the brain. This is helpful in the diagnosis of M.S. and aids in determining the disease's progression over time. The effectiveness of a specific medication on the speed of nerve transmission is also measurable in this way.

Once this information is stored in the computer, Dorfman can program the machine to analyze it in various ways in order to understand more about the nerve signalling process.

***

Epilepsy is a neurologic disorder affecting as many as four million people in the United States today. Most respond favorably to medication, but about 50% still have seizures with some regularity and many are significantly disabled by the disorder.

"The major goals of epilepsy research," says David Prince, professor and chairman of the Department of Neurology, "Are to discover the basic abnormalities in the nerve cells which underlie seizures, and to develop new drugs to treat patients whose attacks are resistant to available therapies."

Prince explains that epilepsy, like many other neurologic disorders, involves an abnormality in communication between neurons or nerve cells. "Instead of the brain processing signals in an orderly way, large groups of neurons occasionally begin to discharge. These have an excessive excitatory influence on larger and larger groups of neurons. Without the braking effect of normal processes which quite nerve cells, an epileptic seizure would result," he says.

Scientists still do not understand what exactly causes epilepsy. "We can produce epilepsy artificially in animals' brains using many techniques, but we don't know which abnormalities are present in the brain of a patient with epilepsy," Prince says.

He and his colleagues in Stanford's epilepsy research group are constantly studying the processes which may occur before epilepsy develops so that they might be able to intervene and halt the disordér before it begins. They are also looking at the possible detrimental effects of epileptic discharges on the developing brain.

Treatment of patients with epilepsy has improved over the past few years with the development of new drugs which are effective in helping control seizures for more people. Also, doctors are better able to observe the frequency of seizures over a long period by having patients use a portable tape recorder-like device developed at Stanford to measure the patients' brain waves for 24 hours. In addition, the device is useful in determining the effectiveness of a particular drug in reducing the number of seizures.

Techniques for measuring exact levels of anticonvulsant drugs in the bloodstream have also allowed significant improvement in controlling attacks in many patients. Everyone metabolizes drugs at a different rate. Measurement of blood drug levels may help guide therapy by allowing doctors to determine if the drug dosage is at the correct level for an individual.

FOR FURTHER INFORMATION CONTACT: Harriet Baumgarten 415: 497-6911

STANFORD--Stanford University scientists engaged in recombinant DNA research have devised experiments which may prove scientifically that many of the feared hazards of the controversial gene-splicing technique do not exist and that ways can be found to avoid potential risks.

Ronald Davis, assistant professor of biochemistry at Stanford University School of Medicine, said experiments done under controlled conditions negate the fear that scientists could create an organism in the laboratory that could take over the world.

Davis and his colleague, John Cameron, in an experiment described in the current issue of Science, combined genes from a simple organism, baker's yeast, with a virus that can grow in bacteria called lambda bacteriophage.

Their purpose was to see if any one gene or group of genes would make the bacteriophage grow better than the original organism. To do this, they inserted virtually every gene from the yeast, a common organism known to be harmless to humans, into the bacteriophage chromosome.

They then grew the resulting organisms containing recombinant DNA for many generations until the strongest one emerged. That one gene, from the perhaps 10,000 genes in yeast, allowed the bacteriophage to grow best.

However, when the original organism was also added to those containing recombinant DNA it always emerged as the strongest organism. Therefore, no recombinant DNA can be made from yeast that will result in better growth for the organism, Davis and Cameron conclude.

Davis said scientists have suspected that the effects of DNA recombination on the growth of organisms ranges from having no effect at all to having a detrimental one. Davis' and Cameron's work demonstrates this in an absolute, scientific way for one organism--yeast. But Davis said that preliminary experiments with higher organisms show that they, too, make bacteria grow worse, not better.

Davis and W. David Benton, as well as Luis Villarreal and Paul Berg, all of the Department of Biochemistry, in two separate experiments described in the same issue of Science, have demonstrated methods for screening DNA recombinations. The advantage of this technique is that scientists will now be able to find the sequence they're looking for quickly, without a random search. By minimizing the number of gene manipulations, the potential hazards that might be present are greatly decreased, Davis said.

STANFORD--On an average day at Stanford University Hospital, 66 new patients check-in and another 65 undergo surgery.

More than a thousand prescriptions are filled in the hospital's pharmacy in a day, and more than 4,000 laboratory tests performed.

The average patient in the hospital in 1960 stayed about 13 days; today the average stay is 7.5 days.

These facts and figures about Stanford Hospital, Clinics, and Medical School have been published in a new 24-page leaflet, called "Facts," now available to the public.

The 618-bed hospital today admits more than 24,000 patients annually, compared to 9,700 in 1960, its first year of operation.

The number of visits to the outpatient clinics has risen steadily from 20,000 in 1960 to more than 130,000 in 1976.

In the medical school, 5,117 students applied for admission in the current first-year class, but only 86 were enrolled--58 men and 28 women. Twenty are minority students (Black, Chicano, or Native American).

A total of 409 students are studying for their M.D. degrees at the medical school; 160 more are studying for other advanced degrees. There are also 268 postdoctoral trainees pursuing advanced studies in the medical school.

Tuition for medical students stands now at $1,644 per quarter. It had been just $50 in 1920, when the medical school was located in San Francisco. It was $335 in 1960 when the school moved to the Stanford campus.

The students' sources of support include loans (43%), scholarships (32%), their parents (8%), their own income (5%), and spouses income (5%).

Fulltime faculty members in the school number 419, and there are another 1,261 voluntary clinical faculty, community physicians in the area who donate a portion of their time to teaching in the school.

Patient care is also supported by 750 medical staff, 395 interns and residents, and almost 3,000 hospital employees.

The hospital is a private nonprofit corporation, owned and operated by Stanford University. According to the "Facts" booklet, 98 percent of hospital revenue comes from patient services. Total revenue for the hospital amounted to $66,511,000 during fiscal 1976.

The annual budget for the school of medicine and the clinics totaled $58,474,576, including more than $26 million in sponsored research and $2 million for plant improvement.

Federal support accounted for 15% of those funds; professional service income 36%; endowment income 10%; tuition and fees 7%; and gifts and grants 15%.

The funds were spent primarily on instruction (41%), patient care (36%), student aid (11%).

"Too often a physician's treatment doesn't work because of a gap in doctor-patient communication," said Dr. Barbara Korsch, professor of pediatrics at the University of Southern California.

She delivered her remarks at the fourth annual Katharine D. McCormick Distinguished Lecture, Thursday, April 14 at Stanford University School of Medicine.

"If doctors fail to meet their patients' expectations, and patients do not feel the physician has understood their concerns, they are less likely to follow the doctor's orders," Korsch said.

Modern patients see themselves as consumers of medical care, are better-educated and demand more from their doctors, she said. They want to take part in the decisions about their own medical care. And doctors need to be equipped to deal with this modern patient.

Communications training should begin in medical school, she said. "All experienced physicians feel they have good rapport with their patients and think they can teach this to medical students by example. But this doesn't work. Communication is a learned skill that involves the brain as well as the heart," Korsch said.

She said doctors should use open-ended questions and a non-judgmental approach in talking with patients. Instead of asking, "Are you giving your child the medicine I prescribed?" to which most parents would answer "yes" automatically, she suggested asking, "How much of the medicine was your child able to take?"

This type of questioning elicits a more honest response and doesn't put anyone on the defensive, Korsch explained.

The key, Korsch feels, is that doctors must determine what the patient needs to communicate in addition to being concerned about what the doctor needs to know.

Dr. Korsch obtained her M.D. degree at Johns Hopkins University. She has been on the faculty at Cornell Medical College and at UCLA, and has been professor of pediatrics at USC since 1969.

The McCormick Lectureship was established in 1974 by the Professional Women of Stanford Medical School with the aim of bringing outstanding women physicians and scientists to Stanford.

The lectureship honors the late Katharine Dexter McCormick, who left a large bequest to the Medical School in 1967 particularly "for the encouragement and assistance of women in pursuing the study and teching of medicine and medical research."

STANFORD--The use of anesthetics may make possible deep sea diving without the nervous system disorders caused by high pressure, according to a study conducted by researchers in the Department of Anesthesia of Stanford University School of Medicine.

Deep sea divers descending below 650 feet often develop tremors and other nervous disorders known as High Pressure Neurological Syndrome. It is thought the effects may be due to the pressure itself.

Researchers Joan J. Kendig, James Trudell and Ellis N. Cohen suggest that addition of anesthetic gases such as halothane and methoxyflurane to the breathing mixture of divers may reduce or eliminate the nervous disorders.

Dr. Kendig said gaseous anesthetics seem to restore fluidity to nerve cell membranes made rigid under high pressure.

"Anesthetics are thought to depress impulse conduction by impairing the flow of ions across the nerve cell membrane," explained Dr. Kendig. Ion flow sets up the electrical impulses which code neuronal messages.

"The anesthetics may disrupt this process by introducing disorder into the lipid components of the cell membrane, or by causing conformational changes in proteins within the membranes," Dr. Kendig said.

She feels that high pressure may oppose these actions either by making the cell membranes more rigid, or by compressing the membrane proteins back into a shape more favorable for transmission.

To confirm either theory, the Stanford scientists are studying the changes in the structure of artificial membrane preparations under high pressure conditions and applied anesthetic agents.

A device called the electron paramagnetic resonance spectrometer measures the motion and angle of rotation of labelled fatty acids in the membranes by recording the spectra of the labels. These two parameters are a measure of the fluidity, or relative disorder, of the cell membrane.

"The effects we observe on the membrane occur somewhere above thirty atmospheres (500 pounds of pressure per square inch)," said Kendig. "That corresponds to about 1,000 feet below sea level."

She said further studies are in progress to determine if these findings are relevant to the problems of deep sea diving.

The research is funded by the U. S. Navy and the National Institutes of Health.

Kendig said the Navy is interested in the application of the study to very deep dives as well as to submarine and diving accidents, where people sometimes must be treated for injuries before they are decompressed.

STANFORD--An educational program for diabetic patients at Stanford University Medical Center has been implemented by the Diabetic Patient Teaching Committee and Nursing Service.

Members of the committee who compiled the program and other nurses at Stanford have found that many diabetics know very little about their disease. Lack of knowledge can frequently result in complications requiring hospitalization which might otherwise be avoided.

To help keep diabetics out of the hospital, committee members designed an educational program for any diabetic who is admitted for diabetes or any other cause.

The committee has supplied each nursing unit with a Diabetic Reference Guide which contains a thorough review of all aspects of the disease for nurses, as well as teaching material for use with patients. Once the physician orders diabetic teaching, the patient's knowledge of the disease is assessed by means of a questionnaire. Nurses then individualize instruction to suit the patient's needs. A patient's progress becomes part of his medical record so that if he is readmitted the education program can be continued where it left off.

Topics in the course range from diabetic coma to the various types of drugs used by diabetics, complications of the disease, advice on diet, travel and exercise, and a discussion of the psychological effects of diabetes. A reading list is also included.

Members of the Diabetic Patient Teaching Committee are: R.N.s Elizabeth Donahue, Susan Franklin, Karen Girton and Sarah Gregg; public health nurse Elizabeth Taft; and dietician Patricia Wood. Doctors from the medical school and the community provided guidance in the preparation of the program.

FOR IMMEDIATE RELEASE

STANFORD –

Dr. Robert A. Chase has resigned as president and director of the National Board of Medical Examiners, and will be rejoining the faculty of Stanford University School of Medicine in September 1977.

A world leader in surgery of the hand, Dr. Chase will have joint appointments as holder of the Emile Holman professorship of surgery, and professor in the department of structural biology.

Chase's appointment was announced recently by Dr. Clayton Rich, dean of the school of medicine and vice-president for medical affairs.

Chase specializes in reconstructive surgery of the hand, and is also well known for his teaching and leadership in medical curriculum innovation, residency training, and continuing medical education.

He served as chairman of the department of surgery at Stanford from 1963 until his appointment to the Board in 1974. He also served as acting chairman of the anatomy department during 1974.

A native of Keene, N.H., he is a graduate of the University of New Hampshire (1945) and Yale University School of Medicine (1947).

As a member of the department of structural biology, Chase will participate in the teaching of human anatomy, and will be involved in developing new methods and materials for that subject.

He expects to combine knowledge of anatomy and surgery and his interest in audio-visual tools toward the development of new programs for postgraduate education.

Chase is a member of the Institute of Medicine of the National Academy of Sciences, past chairman of the surgical council of the American Board of Medical Specialties, and the international relations and graduate education committees of the American College of Surgeons.

STANFORD--One of the most stressful things in life that people have to cope with is serious illness or injury to themselves or a member of their family.

How humans deal with these situations is the theme of a book of writings by various experts edited by Dr. Rudolph H. Moos, professor of psychiatry and behavioral sciences at Stanford University School of Medicine.

The book, Coping with Physical Illness (Plenum Medical Book Company, New York, 1977. 440 pages, $25), written in collaboration with Vivien Davis Tsu, is designed to help those in nursing, medicine and public health to work more effectively with patients and their families who are experiencing serious illness.

Personal essays by people who have coped with illness are included. Among these is a description of how Marvella and Birch Bayh coped with breast cancer, how a family in Maine dealt with a diagnosis of Lou Gehrig's disease and one fifteen-year-old's experience with chronic kidney disease, dialysis and transplant.

Sections on coping with stillbirth and birth defects, cancer, cardiovascular disease, severe burns and chronic illness are included. The emotional strain on professional staff and issues related to death and dying are described also. The stress of medical treatment is explored, emphasizing the importance of unusual hospital environments and radical new treatments such as transplants.

Dr. Moos is chief of psychiatric research at the Palo Alto Veterans Administration Hospital. He was awarded the Hofheimer Prize by the American Psychiatric Association in 1975 for his book, Evaluating Treatment Environments: A Social Ecological Approach.

STANFORD –

Dr. Barbara Korsch, professor of pediatrics at the University of Southern California, will present the fourth annual Katharine D. McCormick Distinguished Lecture Thursday, April 14, at 4:15 p.m. in the Fairchild Auditorium at Stanford University School of Medicine.

She will discuss "Gaps in Doctor-Patient Communication." Members of the medical community and the public are invited to attend.

Korsch plans to discuss "communication gaps," such as doctors' failure to fully explain the nature of patients' illnesses and the needs for particular treatments. Lack of communication, she has reported, may account for many instances of treatment failure. Korsch will describe her investigations of doctor-patient communication with videotape illustrations.

Born in Germany, she received her secondary education in Sweden and the U.S., and attended Smith College. She obtained her M.D. degree at Johns Hopkins University, and served internship and residency at Bellevue, the Mary Imogene Basset Hospital, and the Menninger Clinic.

She has been on the faculty at Cornell Medical College and at UCLA, and has been professor of pediatrics at USC since 1969.

Korsch received the Dart Award for academic innovation at USC in 1974, and in 1973 she delivered the George Armstrong Memorial Lecture of the Ambulatory Pediatric Association. The Texas Pediatric Society has made her an honorary citizen of Texas.

The McCormick Lectureship was established in 1974 by the Professional Women of Stanford Medical School with the aim of bringing outstanding women physicians and scientists to the School.

The lectureship honors the late Katharine Dexter McCormick, who left a large bequest to the Medical School in 1967, particularly "for the encouragement and assistance of women in pursuing the study and teaching of medicine and medical research."

FOR IMMEDIATE RELEASE

STANFORD –

Combining the use of an amphetamine, commonly know as "speed," with morphine can substantially relieve pain in surgical patients, while minimizing the side effects of morphine alone, according to a recent study.

Reporting in the current issue of *The New England Journal of Medicine,* researchers in the Cooperative Analgesic Study Program said pain relief was definitely improved with lesser amounts of morphine as amphetamine was added.

In addition, the greater pain relief was without the undesirable side effects often associated with morphine, such as nausea, respiratory depression and general lethargy

Authors of the report are Drs. William H. Forrest, Jr., Bryon W. Brown, Jr., and Colin R. Brown of Stanford University School of Medicine, and eight other researchers from Tufts, Yeshiva, Indiana, and Miami schools of medicine. Forrest is chairman of the Cooperative Analgesia Study, which has been underway in six Veterans Administration hospitals for several years.

In the study, a group of 450 young patients in the veterans hospitals, mean age of 35, were given morphine or morphine plus dextroamphetamine to relieve severe pain of abdominal or orthopedic operations.

Dextroamphetamine is a white crystalline compound that is a central nervous system stimulant. Morphine, on the other hand, acts as a sedative.

The dose combinations, researchers reported, were considerably more successful than expected.

"It seems clinicians have overlooked a truly effective combination that comes much closer than any existing single compound to offering ideal pain therapy for this group of patients," according to the report.

The authors note that the drug combination could be particularly important for physicians, since it should enable postoperative patients to resume some activity more rapidly, reducing the chance for respiratory or circulatory problems.

Although there were similar findings in studies done 30 years ago, the drug combination has never become a clinical tool for relief of pain.

The authors say this might be because "physicians do not want to subject their patients to the risk of abuse if these drugs are used."

Yet, they report, "it is rare for analgesic drugs to lead to abuse in patients with acute postoperative pain."

Forrest admits he is puzzled why this particular combination was never used clinically, but says current research has been in the direction of using stimulants, or mood-altering drugs, as analgesics.

In an editorial in the same issue, Dr. Leroy D. Vandam of Peter Bent Brigham Hospital, Boston, cautioned about possible cumulative effects and addiction. whether the combination would be safe for the elderly, and whether patients might really want postoperative alertness.

But he noted that the knowledge of mechanisms at work should be useful to future trials, and called for further such work.

The research was supported in part by grants from the Veterans Administration and the National Academy of Sciences-National Research Council.

STANFORD –

Alumni of the Stanford University School of Medicine will gather for their spring reunion day on Saturday, June 4, at the Medical School.

In a morning clinical symposium, speakers will be Dr. John G. Nicholls, professor of neurobiology, on "Cellular Organization of the Brain"; Dr. Eric M. Shooter, chairman of neurobiology, on "Nerve Growth Factor"; and Dr. Dora B. Goldstein, adjunct professor of pharmacology, on "Drug Tolerance and Physical Dependence."

Dedication of an "alumni green" and reminiscences of the old school, formerly located in San Francisco, and the present school of medicine, will be held at noon, with luncheon following for alumni, associates, spouses and faculty.

The afternoon keynote address will be given by Dr. Victor Fuchs, professor of economics at Stanford and vice-president for research and codirector of the west coast branch of the National Bureau of Economic Research. His topic will be "From Bismarck to Woodcock: The 'Irrational' Pursuit of National Health Insurance."

An open house and tours of laboratories in the Sherman Fairchild Center will be held in the afternoon.

STANFORD--The Robert Wood Johnson Foundation has awarded a $272,498 grant to Stanford University Medical School in support of a three-year research and training program in ambulatory pediatrics.

The study is under the direction of Dr. Ruth T. Gross, chief of the pediatric outpatient clinic at Stanford and director of the division of ambulatory pediatrics at the medical school. Co-investigator is Dr. Thomas F. Anders, associate professor of psychiatry and pediatrics and head of child psychiatry at Stanford.

According to Gross, pediatricians frequently continue to treat patients into adolescence, yet may not be equipped to handle the special problems of this age group. In order for the pediatrician to best help the adolescent, Gross says, the issue of what content is needed in training programs for pediatric residents must be resolved.

The research and training program is an outgrowth of a planning project, also funded by the Robert Wood Johnson Foundation, in which investigators worked in conjunction with the Palo Alto Unified School District.

The three-year program will add to existing knowledge about school-related adolescent health problems, including methods for diagnosis and treatment of these problems. A small number of future clinical faculty will be trained in adolescent pediatrics and the course content of training programs for child health providers will be expanded to permit them to more adequately meet the need of adolescents.

The fourth and final lecture of the Progress in Medicine series on cancer will be held at 7:30 p.m., Wednesday, June 1, 1977 in the Sherman Fairchild Auditorium of the Stanford University Medical Center.

The lecture, "Cancer and the Individual: The Effect on Patient and Family," will be a panel discussion moderated by Don R. Goffinet, M.D., assistant professor of radiology. The lecture is open to the public.

Members of the panel are: Suzanne S. Miller, R.N., clinical oncology nurse coordinator; Frank E. Stockdale, M.D., associate professor of medicine and biological sciences, division of oncology; Frederic J. Van Rheenen, M.D., clinical assistant professor of psychiatry; Isabel Walker, R.N., M.S.W., clinical social worker, division of oncology; and Ernle W.D. Young, Ph.D., chaplain to the medical center.

The Progress in Medicine lecture series was initiated in 1966 to provide an opportunity for leaders in academic medicine at Stanford to share information and insights with members of the community.

STANFORD –

Stanford University Hospital's new north wing, which houses an intensive care unit, new emergency department, X-ray facilities, and other laboratories, is now open and receiving patients.

The new Hospital addition is located to the left of the medical center's main entrance. New diagnostic radiology facilities, the emergency department, and blood transfusion and coagulation laboratories are located on the first floor. On the second floor are the intensive care unit, cardiovascular and special radiology facilities, surgical pathology laboratories, and the postanesthesia recovery area.

Although only eight beds are initially in use in the new North ICU, the unit will eventually accommodate 25 beds. This will increase the total number of ICU beds in the Hospital to 47, according to ICU medical director Dr. Myer H. Rosenthal.

North ICU beds are reserved for cardiovascular surgery patients, says Rosenthal, while other surgical and medical patients are treated in the original ICU.

"The new unit provides us much more flexibility," comments Rosenthal, "because it has much more space than our other unit. It also contains the latest monitoring equipment. There is a brighter environment overall, which is good for the patients and staff alike."

An open spaciousness characterizes the new facility, which has been designed with extensive use of glass, both as part of the exterior and within patient areas.

The new emergency department, for example, is almost twice the size of the old, with 18 treatment rooms and a special acute resuscitation room featuring modern wall-mounted equipment panels.

Both the new ICU and the emergency have designated special areas where families of patients may confer with doctors privately. The comfortably furnished Leonard Consultation Room and Lounge adjacent to the ICU is named for W. Drew and the late Mrs. Leonard, former Stanford Hospital patients.

Both inpatients and outpatients will be accommodated in the radiology area, according to Dr. William H. Northway, director of the division of diagnostic radiology. The unit is designed in the pattern of concentric "c's" with convenient access for outpatient general radiography, and interior rooms for inpatient procedures such as tomography, head and body scanning, and ultrasound. At the center of the unit are processing areas and radiographic viewing areas.

"Besides the increased space and new equipment, there is a real benefit in better work flow and more efficient patient care," comments Sandra Noon, chief technologist. "This should mean much less waiting time for patients."

The new blood transfusion and coagulation laboratories were constructed in the new wing with a grant from the William Randolph Hearst Foundation.

The transfusion service is the largest in California. Its purpose is to ensure the compatibility and safety of all blood transfused at the Hospital and at Children's Hospital at Stanford.

The coagulation laboratory staff makes rapid identification of coagulation deficiencies in surgery patients and consults on medical and presurgical cases, the treatment of hemophilia, and dosage control of patients receiving anticoagulants.

Laboratories and patient-care services in the new wing will continue to be phased into operation as equipment is installed during coming weeks.

Still under construction is a level bridge linking operating rooms in the original building with the new wing's postanesthesia recovery area. The bridge is expected to be completed early this summer.

In addition, plans for utilization of shell space will be developed.

According to Paul Hofmann, director of the hospital and clinics, the "catch up" expansion will relieve overcrowding in laboratory, X-ray, and other hospital support departments.

As departments have relocated out of the original building, work has begun in renovating those areas. The former emergency area is now being designed to accommodate a new oncology day-care center for treatment of cancer patients. Central services on the ground floor of the hospital and clinical laboratories on the second floor are also being expanded.

Total cost of the project is $18.1 million. Original plans called for a construction budget of $12.6 million, excluding activation and new program costs. However, a variety of code and licensing deficiencies caused delays and increased costs. These are being contested in a claim for an undisclosed amount against the architectural firm of Caudill Rowlett Scott of Houston.

STANFORD--A state health department official said Friday, May 20, that Stanford University Hospital "has no serious hazards" despite a checklist of "deficiencies" found by inspectors last January.

Thomas Callahan of the State Department of Health district office in San Jose, after a meeting with hospital officials, said that most of the deficiencies listed in a state report already have been corrected or are in the process of being resolved.

The report listed 43 items, many relating to longstanding problems of insufficient space at the hospital for its annual full load of patients and the needed supplies and equipment.

During the Friday meeting, Callahan deleted five of the items because, he said, the inspection team that toured the hospital in January had insufficient or inaccurate information.

One item mentioned in the report included the need to separate contaminated linen from incoming supplies in loading areas and corridors.

But Peter Levin, associate vice president for medical affairs, noted it was not a matter of incoming and outgoing materials coming into direct contact, since "everything is wrapped and covered."

In addition, a partition has been constructed down the wide corridor in question, thus creating two one-way corridors, he said.

Hospital deputy director Gary Mecklenburg said he feels it is "important to note that the quality of patient care has not been questioned" in the report. Callahan agreed.

Many of the items related to record keeping, a problem which has been addressed, Mecklenburg said.

For example, one item that cited 2,150 "delinquent records for discharged patients" meant that records had not been closed within the mandated 14-day period. Many of the delinquencies were just a few days, and since the survey in January the total has been reduced to about 500, said Mecklenburg. This is appreciably lower than the acceptable rate suggested by the Joint Commission on Accreditation of Hospitals.

Both Mecklenburg and Levin said some of the space items cited in the report will be around for several years, but others are in the process of being resolved. A central storage area for sterile items has been created in the basement of the new hospital wing which opened this spring.

Plans are under way to renovate the neonatal intensive care nursery, and a review is under way of all areas needing upgrading, officials said.

STANFORD –

Dr. David P. Rall, director of the National Institute of Environmental Health Sciences and an assistant surgeon general, will speak at Stanford University Medical Center Thursday, May 26.

His address, which is entitled "The Environment, Human Health, and the Medical School," will begin at 4:30 p.m. in the Sherman Fairchild Auditorium and is open to the public.

A clinician's response to Rall's address will be delivered by Dr. Daniel Federman, professor and chairman of the Department of Medicine at Stanford.

Rall's talk honors Dr. Rodney R. Beard, a member of the Stanford medical faculty since 1940, who is retiring.

Beard, a Stanford graduate with both his A.B. degree and medical degree, has distinguished himself in the fields of environmental and preventive medicine and occupational health.

He was chairman of the Department of Preventive Medicine from 1949 to 1969, shared in the development of the five-year curriculum at Stanford Medical School, and organized the Stanford Rehabilitation Service.

Beard has specialized in studies of the effects of toxic agents on human behavior (particularly carbon monoxide). He is a consultant for federal and state air pollution control groups, environmental epidemiology and occupational health, and the education of preventive medicine specialists.

Rall earned his M.S., Ph.D. and M.D. from Northwestern University. He has coauthored and authored over 100 published papers relating to comparative pharmacology, cancer chemotherapy, blood-brain barrier, blood CSF barrier, pesticide toxicology and drug research and regulation.

Rall formerly served as associate scientific director for experimental therapeutics of the National Cancer Institute (1966-71).

STANFORD--Dr. Henry S. Kaplan has been selected to receive the Leopold Griffuel Prize, awarded by the Association for the Development of Cancer Research at Villejuif, France.

Mr. Jacques Crozemarie, president of the association, will formally present the prize to Kaplan at Villejuif, on the outskirts of Paris, June 21. He will be honored at a reception at the French consulate in San Francisco, May 20.

Dr. Kaplan, Maureen Lyles D'Ambrogio professor of radiology and director of Stanford's Cancer Biology Research Laboratory, is an internationally-known authority in clinical and basic cancer research. He conceived the use of the linear accelerator for medical purposes and helped to design it. His pioneering radiotherapy techniques have resulted in dramatic gains in the treatment of certain cancers, particularly Hodgkin's disease and other malignant lymphomas.

Kaplan is now involved in research which will expand his earlier discovery that radiation-induced leukemias in mice are caused by a latent virus triggered by the radiation exposure. He is looking at several aspects of the biology of human malignancies, with emphasis on the possible role of viruses as the cause of cancer.

Among Kaplan's honors are the 1969 Atoms for Peace Award and election in 1972 to the National Academy of Sciences. He was made a Chevalier de la Legion d'Honneur by the Republic of France and has received Italy's Order of Merit.

The Griffuel prize, established in 1970, is awarded annually for accomplishments in cancer research. It is named for the late Leopold Griffuel who was born in Paris in 1870 and held a doctorate in law in addition to being an M.D. After his death in 1950, Mrs. Griffuel founded the Association for the Development of Cancer Research which awards the 100,000-franc ($20,000) prize.

CITY DESKS: A press conference in connection with the book, *Costs, Risks, and Benefits of Surgery*, will be held at 10 a.m., May 23, 1977 in the President's Room of the National Press Club, Washington, D.C. Dr. John P. Bunker of the Stanford University School of Medicine will discuss the book and comment on the need for new approaches to the evaluation of surgical care.

ADVANCE FOR RELEASE MONDAY, MAY 23, 1977.

STANFORD –

American medicine should adopt a new model for judging the net benefits of surgical care, a Stanford University professor urged Friday, May 20.

The current popular model, which categorizes operations as necessary or unnecessary, was appropriate when surgery—and medicine as a whole—was devoted mainly to the treatment of life threatening diseases, said Dr. John P. Bunker, professor of anesthesia and director of Stanford's Division of Health Services Research.

Now, however, most of these diseases of the past have become curable, and much of surgery is devoted, quite properly, to attempting to improve the quality of life—to relieve discomfort, disfigurement and disability, he said.

"The potential benefits of such treatment may be small," Bunker noted, "but nevertheless important. Similarly, the risks may be relatively small but they also are important."

To measure small benefits or risks requires much more sophisticated methods than were needed to assess treatments for life-threatening conditions of an earlier era, he said.

The Stanford professor also said that a campaign to educate the American public that health care is sometimes faulty would be quite proper.

Bunker expressed his views in remarks prepared for delivery Monday, May 23, at a press conference in Washington, D.C. He will discuss the book, *Costs, Risks, and Benefits of Surgery* to be published next week by Oxford University Press.

Edited by Bunker and Harvard's Benjamin A. Barnes, a surgeon, and Frederick Mosteller, a statistics professor, the 400-page book provides the most comprehensive critique yet of surgical care in the United States. The need for new data on surgery and methods for collecting them are major areas of the book.

"Data which are available, however, and the analyses presented are consistent with the notion of surgical utilization leading to diminishing marginal benefits," Bunker said.

"Since most dollar costs are not borne by patients, risks, when they are small, are largely ignored," he added.

Bunker stated that certain operations, when subjected to cost-benefit analysis, are shown to have little or no effect on life expectancy or improvement of the quality of life.

As an example, he said, elective gall bladder surgery for silent gallstones in a 49-year-old man in good preoperative physical condition will increase his life expectancy by 16 days, in comparison to the predicted life expectancy for the same patient managed medically.

Another study, however, shows that at age 60 the advantage of surgical over medical management for males in good preoperative condition is reduced to seven days. And a poor risk 60-year-old woman has been estimated to lose 14 days of life after elective gall bladder surgery.

Bunker said that for the nation as a whole the difference in cost between radical and simple mastectomy with radiation treatment is probably more than $100 million a year. Yet there is no evidence that the costlier procedure increases life expectancy.

(more) 5/19/77

"The quality of life following radical mastectomy is, in fact, distinctly poorer compared to simple mastectomy if one takes into account its psychic and social costs," he said.

Variations in surgical procedures, according to Bunker, entail substantial costs in dollars and morbidity.

Public and professional attitudes toward surgical care will have to change, he asserted. There is the belief that human life is priceless. No cost should be spared.

"But medical triumphs have created new moral and economic issues," Bunker said. "Coronary artery bypass surgery or kidney transplantation, for example, may be treatments that cost more than society is willing to pay."

Bunker listed four urgent needs that will have to be addressed in making choices for the future:

* Appropriate studies of the effectiveness of surgical treatment should be carried out for selected conditions, particularly when uncertainty leads to professional disagreement.

* Research to obtain reliable data, and improve cost-benefit analysis of surgical procedures should be stepped up.

* Methods of cost-benefit evaluation should be a part of the curriculum of medical schools and incorporated into clinical practice and continuing medical education.

* Information should be compiled and properly presented to the public.

"Pioneering surgeons devised operations primarily on intuition and assessed them by trial and error," Bunker said. "This era produced many brilliant operations, but also some which were discarded after years of application and a large cost in dollars, morbidity and even mortality.

"This was at a time when there was no extensive knowledge in the basic biological sciences or experimental designs that permit logical conclusions from multiple clinical experiences."

The randomized clinical trial should be more widely adopted in surgical research, Bunker said. Even though there are ethical questions in carrying out experiments in humans, there are also serious ethical problems when operations are carried out without proper evaluation.

According to the studies, the costs in dollars and lives of a poor experiment or of no experiment, were often much greater than those of a well-designed and executed clinical trials, Bunker said.

As an example he cited the widespread adoption of gastric freezing for treatment of duodenal ulcer, and of internal mammary artery ligation for relief of anginal pain.

"Both procedures were promptly discarded when they were proved ineffective in a randomized clinical trial," Bunker said.

Commenting on the role of the public, Bunker said:

"Some physicians feel no useful purpose can be served by a campaign to convince the American people that health care is sometimes faulty. Elaborate disclosure is, to be sure, apt to be inappropriate in the presence of immediately, life-threatening disease.

"But the public must be informed of the limits of medical and surgical intervention, especially for those conditions where benefits and risks appear small, and individual personal values are apt to play a decisive role."

END ADVANCE FOR RELEASE MONDAY, MAY 23, 1977.

STANFORD--The lipids, or fats, of nerve cell membranes may be keys to understanding how alcohol affects the human body, according to Stanford researchers.

Recent studies indicate a new emphasis on membrane lipids as a site of long-term drug action. If such lipids are involved, say the scientists, then dietary fats may turn out to be important in the treatment or prevention of alcoholism as they are in heart disease.

Studies of cell membranes may also be useful in discovering how the human body develops tolerance to prolonged use of alcohol, according to Dr. Dora Goldstein, adjunct professor of pharmacology at Stanford University School of Medicine, and Dr. Jane H. Chin, senior research associate, writing in a recent issue of Science.

Their data suggest that membrane lipids are able to adapt to alcohol. This is in contrast to other drugs, such as morphine, which are thought to cause an adaptation involving proteins rather than lipids.

In one study, the researchers fed one group of mice a diet that included a high proportion of ethyl alcohol. The other group of mice had the same diet without the alcohol.

At first, the alcohol-drinking mice looked drunk, but later they developed tolerance to the alcohol.

When alcohol was added to the membranes from the tolerant mice, there was little change, just as their behavior did not show the effect of the alcohol.

The mice also developed physical dependence, meaning that they would go into convulsions when they sobered up completely.

Membranes of red blood cells and of nerve cells from the tolerant mice appeared normal when washed free of alcohol. No change was observed in the membranes that would explain the convulsions, say the researchers.

The response to alcohol that was measured was a change in fluidity of the cell membranes.

According to Goldstein, normal cell membranes have a certain degree of fluidity that must be exactly right for the cell to function properly, especially in the brain.

Alcohol made the membranes of normal mice more fluid, a change that might cause the brain to malfunction. However, the membranes of mice on the high alcohol diet were relatively resistant to this fluidizing effect of the alcohol, suggesting they had adapted to the drug.

Goldstein notes that more studies are needed to examine chemical composition of the alcohol-tolerant membranes.

The research is supported by the National Institute on Alcohol Abuse and Alcoholism.

STANFORD--"Treatments for Cancer: New Therapies" will be the topic of the third in a series of four lectures about cancer, to be held at 7:30 p.m., Monday, May 23 in the Sherman Fairchild Auditorium of Stanford University Medical Center.

The lecture is open to the public.

Speakers will be Dr. Saul A. Rosenberg, professor of medicine and radiology and chief of the division of oncology, and Dr. Sarah S. Donaldson, assistant professor of radiology.

Dr. Rosenberg is also president and chairman of the board of trustees of the Northern California Cancer Program. He has made significant contributions to cancer research, particularly in treating patients with lymphoma. Rosenberg has won several teaching awards, among them the first Arthur Bloomfield award for excellence in teaching. He will be director of Stanford's oncology day care center which is scheduled for Fall opening.

Dr. Donaldson serves in the division of radiation therapy at Stanford. She is involved with radiotherapy-chemotherapy interactions, particularly as applied to children. Among her accomplishments is the development of a special diet to help manage severe intestinal complications which may result from radiation therapy and chemotherapy in children with cancer. She has recently been involved in the study of pregnancies of women who have been treated with radiation therapy for the treatment of Hodgkin's disease.

The Progress in Medicine lecture series was initiated in 1966 to provide an opportunity for leaders in academic medicine at Stanford to share information and insights with members of the community.

The last lecture of the series is a panel discussion on "Cancer and the Individual: The Effect on Patient and Family," June 1, 1977.

STANFORD--A memorial service for the late Dr. Emile F. Holman, whose career at Stanford University spanned more than 50 years, will be held Saturday, May 21, starting at 5:30 p.m. at Stanford's Memorial Church.

Holman, a professor of surgery emeritus, died March 19 at age 86.

Friends and members of the Stanford community are invited to attend the service.

Participants in the memorial service will include Ernle Young, associate dean of Memorial Church and chaplain of Stanford Medical Center; Dr. Victor Richards, president of the Stanford Medical Alumni Association Board of Governors; Dr. James B.D. Mark, professor and head of the Division of Thoracic Surgery, Stanford Medical School; and Peter Olch, deputy chief of the National Library of Medicine.

Olch, who has interviewed leading physicians in the country, will play taped recordings of his interviews with Holman.

A graduate of Stanford with an A.B. degree in 1911, Holman was a Rhodes Scholar and received his M.D. from Johns Hopkins before returning to Stanford in 1925 as an associate professor of surgery. A year later he became professor of surgery and chairman of the department, a position he held until his retirement from the faculty in 1955.

Holman was considered the predominant authority on arteriovenous fistulas and was a major contributor to the development of the surgical treatment of "blue babies." He was the first to perform the operation on the West Coast.

An endowed professorship was named after him at Stanford Medical School--the Emile Holman Professorship of Surgery, established in 1972.

The family has requested memorial donations to sent to the Department of Surgery, Stanford Medical School.

STANFORD--Dr. Edwin G. Krebs, newly appointed chairman of the Department of Pharmacology at the University of Washington School of Medicine in Seattle, will present the fourth annual Windsor C. Cutting Memorial Lecture at Stanford University Medical School.

The lecture, which is open to the medical community, will be given Thursday, May 19, starting at 4:15 p.m. in the Fairchild Auditorium. Krebs will speak on "Protein Phosphorylation Reactions: New Sites for Regulation by Chemical Agents."

On July 1 Krebs will officially become an investigator of the Howard Hughes Medical Institute and Pharmacology Department chairman at Washington. Until then he is serving as a visiting professor of biological chemistry at the University of California, Davis.

A graduate of the University of Illinois, Urbana, Krebs received his medical degree at Washington University School of Medicine, St. Louis, Mo. in 1943.

In 1966 Krebs became professor of biochemistry and assistant dean for planning at the University of Washington Medical School in Seattle, and in 1972 he was appointed chairman of the Division of Basic Sciences at U.C. Davis School of Medicine.

Krebs has concentrated his research into the regulation of carbohydrate metabolism and related studies in glycogenolysis, which is the splitting up of glycogen in body tissues that yield glucose.

Krebs is a member of the National Academy of Sciences and was a recipient of the Distinguished Lectureship Award of the International Society of Endocrinology (1972), and the Annual Faculty Research Lectureship at U.C. Davis (1975-76).

The Windsor Cutting Lectureship was established in 1973 by the faculty of the Department of Pharmacology and is supported by private contributions. It honors the memory of Dr. Cutting, professor and former chairman of the department, who also served as dean of Stanford Medical School, 1953-57, and as dean of the University of Hawaii Medical School, 1963-71. Dr. Cutting died in 1972.

The lectures, which feature speakers prominent in the field of pharmacology, are given annually.

FOR IMMEDIATE RELEASE

STANFORD –

Program plans for renovating and upgrading Stanford University Hospital's neonatal intensive care nursery were approved by the University Board of Trustees at their meeting Tuesday, May 10, 1977.

The Board also gave its approval to preliminary plans for expanding certain molecular biology laboratories involved in recombinant DNA research in the School of Medicine.

Renovations in the nursery will increase space for bassinets and support services as required by new State Department of Health standards, and also provide needed space for the comprehensive services of the unit, according to Paul Hofmann, director of Stanford University Hospital and Clinics.

More than 750 critically ill infants are admitted annually to the unit from throughout the western states. There are 25 bassinets, including four in the premature clinical research center.

The unit conducts comprehensive teaching programs in developmental biology and neonatology for postdoctoral Ph.D. and M.D. trainees, fellows, residents, and medical students.

Research projects in the unit include studies in extrauterine growth and adaptation, regulation of enzyme action during development, and sudden infant death

According to Dr. Clayton Rich, vice-president for medical affairs and dean of the School of Medicine, the expansion of molecular biology laboratory space will allow continued development of research programs in bacterial plasmids. The laboratory space will be utilized by Dr. Stanley Cohen, professor of medicine, and by faculty of the Department of Genetics.

The project calls for added laboratory space for Dr. Cohen on the third floor of the Lane Building of the Medical School, near the Department of Genetics.

Included in the plan is a P-3 facility, to be located on the third floor of the adjacent Grant Building. P-3 refers to the degree of physical containment required by National Institutes of Health guidelines for laboratories conducting specific types of recombinant DNA research.

Further plans for design and funding of both nursery and laboratory projects will be under way during the next several months.

Projected cost of the nursery remodeling is in the range of $900,000 to $1,000,000. Gift funds are expected to support a portion of the costs.

The molecular biology laboratories and associated relocation of other facilities is expected to be in the range of $800,000 to $950,000, to be supported by Medical School resources and gifts.

STANFORD--As employees of Stanford University Medical Center's Finance Department sit around enjoying sack lunches they have often been treated to strains of Haydn's "Divertimento in C Major" or Bozza's "Trois Mouvements."

And, although some employees may compare them with the New York Woodwind Quintet or even the Melos Ensemble of London, they are actually the finance department's "adopted" woodwind quintet.

As yet, the group does not have a name. Nevertheless, its members believe they will soon be performing publicly.

"We're serious about our music," noted group co-founder Lisa Lawrence, a systems analyst in medical center finance. "But we don't want to be so serious that we don't enjoy what we're doing. We have a lot of fun."

Lawrence, along with Linda Wilson, a forms analyst in finance, were both music majors in college (Lawrence at Pomona College in Claremont, Calif. and Wilson at Ohio State). Neither had played seriously for four years when they struck up an acquaintance in the finance office and eventually decided to organize a musical group.

"We thought it was a good idea to start up our musical playing again," Wilson recalled, "And once we started we discovered how much we actually enjoyed it."

Originally a duet, Lawrence (flute) and Wilson (clarinet) gave a recital for five "close and uncritical friends" and later performed as part of a church service. They also played at an employee Christmas party held last year at Stanford Hospital.

"Our ultimate goal was to form a quintet because the repertoire for flute and clarinet is very limited," Wilson explained. So they eventually added three new members--Leonard Winograd, a photographer in the Dermatology Department in the medical center (oboe); Jack Johnstone, a graduate student in music at San Jose State (bassoon); and Lloyd Banta, an electrical engineer at Varian Associates (French horn).

Once a quintet, the "no name" group had problems lining up suitable practicing sites.

"For a while we practiced in the (Stanford Hospital) print shop," Lawrence noted. "It was the only place nearby where everyone cleared out at lunchtime with no one next door for us to bother. Of course, sometimes we did have to practice with the machines running, which was difficult because those darn machines wouldn't follow our tempo." (As a duet Lawrence and Wilson had also practiced outside the university mausoleum--burial site for Sen. Leland Stanford, his wife Jane and son Leland Jr., which is near the medical center).

The quintet, which ranges its repertoire from classical to contemporary selections, also practices in the finance complex on occasion. But it usually meets once a week alternating between members' homes. ###

STANFORD--"Eye Dazzler," a mural composed of over 200,000 pheasant feathers, has been installed in the Sherman Fairchild Center Auditorium at Stanford University Medical Center.

The feathers derive from the Lady Amherst and Golden Pheasant varieties that have been stapled and glued to the mural's plywood backing.

The mural, which is enclosed in plexiglass and measures approximately 12 feet by eight feet, was created by artist Nicki Marx of Santa Cruz. Marx was commissioned by the medical center to assemble the art work for the auditorium, which is part of the new Fairchild complex for neurosciences research. The complex opened late last year.

The mural's feathers, which are from non-endangered pheasants raised commercially, are assembled to reflect an "optical, in-motion quality," Marx noted. "The name 'Eye Dazzler' is also a reference to the unique Navajo rugs of the late 1800s which have the quality of motion in design and the use of vivid colors," she said.

Marx, who is represented in Palo Alto by Smith-Andersen Gallery, said her work is also a "personal celebration of life, and an exploration of natural materials. The work is connected to ancient traditions from many lands, yet is unique in its application of materials to modern forms and ideas."

Selection of the mural for the Fairchild Auditorium was coordinated through an art committee appointed by Dr. Clayton Rich, vice-president for medical affairs and dean of Stanford Medical School. Committee members are Dr. Joseph Kriss and Henry Kaplan, radiology, and William Fielder, clinical assistant professor of surgery at Stanford. Consultant to the committee is Dr. Albert E. Elsen, art history.

STANFORD--Stanford University School of Medicine has received a gift of $1 million from the James G. Boswell Foundation of Los Angeles for rehabilitation and expansion of departments within the Boswell Clinic Building of the medical center.

The funds will allow major improvements to be made in the 18-year-old facility for both outpatient care and clinical research programs, according to Dr. Clayton Rich, vice-president for medical affairs and dean of the school of medicine.

Most of the medical center's 60 outpatient clinics are located in the building, including general medical clinics, pediatrics, gynecology and obstetrics, surgery, and radiology treatment areas. They receive more than 130,000 patient visits each year.

One of the first uses of the new gift will be the remodeling and expansion of gynecology and obstetrics areas on the third floor, according to Dr. Rich.

The Boswell funds will be earmarked for other clinical areas in the next several months, according to Dr. Rich, as needs are identified.

STANFORD--"New Ways to Diagnose Cancer: The Impact of Technology" will be the topic of the second in a series of lectures about cancer, to be held at 7:30 p.m. Wednesday, May 11, in the Sherman Fairchild Auditorium of Stanford University Medical Center.

The lecture is open to the public.

Speakers will be Dr. I. Ross McDougall, associate professor of radiology, and Dr. Leslie M. Zatz, professor of radiology.

Dr. McDougall has served in the Division of Nuclear Medicine at Stanford since July 1976, and was formerly lecturer in medicine at the Glasgow Royal Infirmary, Scotland. His clinical interests are related to endocrine diseases, organ imaging and detection of cancer. His research has focused on methods of computer-assisted imaging and portable techniques which can be used at the bedside.

Dr. Zatz, chief of radiology at the Palo Alto Veterans Administration Hospital, also serves in the Division of Diagnostic Radiology at Stanford. His subspecialty interest is neuroradiology. Since coming to Stanford in 1958 his research has been in developing new tools and instruments for diagnosis. He has worked with experimental ultrasound cameras and assisted in development of computerized tomography.

The Progress in Medicine lecture series was initiated in 1966 to provide an opportunity for leaders in academic medicine at Stanford to share information and insights with members of the community.

Future topics will include "Treatments for Cancer: New Therapies," May 23, and "Cancer and the Individual: The Effect on Patient and Family," June 1.

###

Mailed Tuesday, May 3, 1977

Science writers: This story describes an important step in cancer virus research. The research, however, is incomplete. There is not yet proof that the virus isolated by Dr. Kaplan and his colleagues at Stanford is a human cancer-causing virus. I direct your attention to the fourth paragraph. Because of these limitations, we ask that you treat this preliminary report cautiously until all the evidence is in.

Spyros Andreopoulos

STANFORD--A team of Stanford University scientists has successfully isolated and purified a virus from the tumor cells of a patient with diffuse histiocytic lymphoma.

The disease is one of the most malignant cancers of the lymphoma group.

The researchers said this was the first reported instance of the spontaneous and sustained release of a virus by a permanently established human cancer cell line.

Dr. Henry S. Kaplan stressed in an interview there is not yet proof the agent is a human cancer virus. "The finding, however, lends plausibility to a search for causation," he added.

Kaplan, professor of radiology, directs Stanford's Cancer Biology Research Laboratory.

The research was reported in the June issue of the Proceedings of the National Academy of Sciences. Kaplan's collaborators are Robert S. Goodenow, Alan L. Epstein, Susanne Gartner, Alain Decléve, and Peter N. Rosenthal.

The scientists said they have confirmed the agent in question is a "C-type" virus containing the genetic material RNA (ribonucleic acid).

The virus has a density identical to known animal C-type viruses that cause leukemias and lymphomas in animals. And it contains an enzyme called "reverse transcriptase" that shows some relatedness to

(continued)

similar enzymes found in several monkey viruses.

This enzyme transcribes the RNA of the virus into a DNA copy, which is then integrated into the cell where the virus can reexpress itself at a later time. Simply stated, it adds to the cell an extra set of genes.

In collaboration with Dr. Jack Griffith of the Department of Biochemistry, the researchers said they had obtained electron microscope pictures of the virus showing similarities to other mammalian RNA viruses.

Moreover, the scientists have shown the virus can change the growth behavior in the test tube of normal cells from Rhesus monkeys and to some extent from man. The human cell experiments, however, are not yet completed.

Monkey cells transformed by the virus," explained Kaplan, "contain chromosome numbers different from normal." This is an important criterion of malignancy.

However, many more steps are required to prove conclusively that the virus has cancer-causing potential, he said.

Among these is an experiment to show that normal cells transformed by the virus will propagate indefinitely as a cell culture, in short, become immortal. Another study involves injecting the cells into "nude" mice, a mutant species permissive for tumor cell growth. The purpose is to show whether the altered cells would grow as a tumor.

In addition, the Kaplan group plans studies by a procedure called molecular hybridization. These would show if the transformed cells had acquired DNA sequences from the genetic material of the tumor cells in which the virus was present.

(Continued)

These experiments, according to Kaplan, would help exclude any possibility of cross-contamination by other viruses and would add weight to the view that the virus may be human.

Kaplan said the search for the virus was facilitated by the establishment at Stanford two years ago of permanent cell lines from the tissue of patients with a diagnosis of histiocytic lymphoma.

Scientists had previously isolated C-type RNA viruses from leukemia patients, but they did not come from permanently established cell cultures. The cells died out, and, in order to be propagated, the virus had to be passed through other species of animal cells. This procedure, however, often alters the virus so that scientists can no longer be certain if it is identical ~~with~~ to the original isolate.

The Stanford cell lines provide a renewable source for many repeat experiments. The cancer cells can be frozen away, thawed and grown as needed, he said.

The scientists began to pick up evidence of particles in the cytoplasm of these cells about two years ago.

"This in itself was a good lead," said Kaplan. "When you find particles containing RNA within the cell, then you have two pieces of evidence pointing you in the right direction."

It was not, however, until the scientists had improved the sensitivity of their biochemical tests that they knew they had isolated a virus with active reverse transcriptase, that the enzyme met all the scientific criteria, and that copy DNA could be made with it in the test tube.

The scientists also confirmed viral activity through co-cultivation of the lymphoma cells with a rat cell known as XC. This is a cell line

(continued)

which carries a defective chicken virus. When XC cells contact some C-type viruses from a mammalian source, they are fused into one giant cell containing many nuclei, "and this is one hallmark of their action", said Kaplan.

Kaplan said his team has concentrated its efforts on RNA viruses because they are known to be the cause of lymphomas and leukemias in certain kinds of mammalian species and chickens.

But replication of RNA viruses is complex, said Kaplan. They hide within the cell and require sophisticated biochemical techniques to get at them.

The test requirements in fact turned out to be somewhat different from those used to detect other enzymes, he said.

The research is supported by grants from the National Cancer Institute, and gifts to the Joseph Edward Luetje Memorial Fund for Lymphoma Research.

STANFORD--The first Charles and Gertie Thuss Lecture, sponsored by the division of plastic and reconstructive surgery at Stanford University School of Medicine, will be held at the medical school on Tuesday, June 28.

Dr. Erle E. Peacock, Jr., professor of surgery at the University of Arizona College of Medicine, will discuss "Biological and Pharmacological Control of Healing and Regeneration" at 4:15 p.m. in the Sherman Fairchild Auditorium.

Members of the medical community and the public are invited to attend.

Dr. Peacock is a well known surgical biologist, a plastic surgeon, and specialist in hand surgery. He has done extensive study in the field of wound healing, in the healing of collagen, the protein of skin, bone and connective tissue, and in the altering of collagen by pharmacologic means.

He served as chairman of surgery at Arizona from 1969 to 1974, and was formerly associated with the University of North Carolina. A graduate of Harvard Medical School (1949), Peacock has authored numerous publications and is active in many national professional organizations.

The lectureship has been established by Dr. Charles J. Thuss, Jr., who is associated with South Texas Pathology Associates in San Antonio, Texas, and Mrs. Thuss, a member of the Stanford class of 1966.

It honors his father, Charles J. Thuss Sr., and his mother, the late Gertrude Noble Thuss, a former registered nurse. Dr. Thuss is in plastic surgery practice at Kaiser Hospital, Santa Clara, and is clinical associate professor of surgery at Stanford Hospital.

STANFORD--Physicians on Stanford University Hospital's medical staff have approved new medical staff bylaws, it was announced Monday night (June 20).

A total of 494 physicians cast mail ballots, with 345 voting in favor of the bylaws, according to hospital officials. There are about 700 physicians on the medical staff.

The bylaws provide a new formal framework for the organization of the medical staff. The bylaws were drafted by a committee composed of faculty and community physicians.

Under the new bylaws the medical staff is responsible to the Hospital Board of Directors for the policies of professional medical care.

Membership on the Medical Board which is the executive committee of the staff has been expanded to include an elected president of the medical staff, five physicians elected by the medical staff at large, the hospital's medical director, and director of nursing services.

In addition, now serving on the Medical Board are the service chiefs, the chief of staff, five deputy chiefs (community) and the hospital director.

The bylaws provide for a closed single medical staff with both community physicians and faculty subject to the same rules covering conduct and discipline.

The new bylaws no longer require that a chief of service (a Stanford Department Chairman) must approve a physician's application for staff membership.

They make it clear that recommendations of the service chief with regard to the physicians' qualifications pertaining to competence, character and ethics will be submitted to the Credentials Committee, then Medical Board, and the Hospital Board of Directors where final decision is made.

A procedure has been added by which the medical staff may override actions of the Medical Board on medical care policy, including the adoption of rules and regulations governing the medical staff.

The new bylaws also provide that future amendments may be made by combined action of the medical staff and the Hospital Board of Directors. The bylaws will become effective after they are approved by the Hospital Directors.

Editors: This release is issued jointly with the University of California-San Francisco School of Medicine.

STANFORD--A new course about common illnesses, called "Mundane Medicine."

A new community-run health service.

A computer databank designed to improve the care of arthritic patients.

These practical projects are among many initiated as part of a joint training program at Stanford Medical School, the University of California-San Francisco School of Medicine, and UC-Berkeley.

The young physicians who designed them are part of the national Clinical Scholars Program, supported by the Robert Wood Johnson Foundation of Princeton, New Jersey.

The foundation recently approved a $799,674 grant for three years to continue the program. There are 15 clinical scholars, nine at Stanford and six at UC.

The scholars have received their M.D. degrees, and have established skills in clinical medicine when they enter the program. The aim is to enrich their future medical work with knowledge in nonbiological subjects--economics, sociology, organization and management, ethics--which they can apply to improve health care.

An advisory committee at each medical school draws on faculty from throughout both universities. Scholars work together in seminars and individually on their own projects with a faculty advisor.

According to Dr. Halsted Holman, professor of medicine and director of the Stanford portion of the program, most of the physicians are interested primarily in the areas of organization of health care, medical sociology and economics, and medical education.

A principal aim, says Holman, "is to bridge the gap between medicine and the community."

One of the major new community programs to result in part from the Clinical Scholars Program is the Mid-Peninsula Health Service (MHS), an independent community-based, cooperatively-run health service. Holman is president of the board of directors. Douglas A. Rund, a former clinical scholar, was the first medical director, and many scholars contribute to its programs.

The aim of MHS, says Holman, is to provide primary, and some specialty, care in ways that will "improve health outcomes, control or reduce costs, and give patients more satisfaction." There is emphasis on self and home care, patient education, reduction of indecisive or redundant

-more-

medical procedures, team care, and the use of nonphysician personnel.

Scholars are also serving in other area health clinics. Dr. June Fisher was an internist at the Charles R. Drew Neighborhood Health Center in East Palo Alto, and is directing its hypertension program.

Fisher is a graduate of Sarah Lawrence College, Barnard College at Columbia, and New York's Downstate Medical Center. During her two years in the Stanford program, she completed a training manual for nurses about hypertension assessment and management, and originated the "Mundane Medicine" course.

Matthew Liang is writing "Mundane Medicine: A Manual for Primary Care," a book directed to medical students and housestaff concerning the 20 most prevalent diagnoses for office-based physicians. He, Fisher, and medical student Michael Crouch, designed and teach the class which has now been expanded to a two-semester subject.

With his preceptor, Dr. James Fries, assistant professor of medicine at Stanford and former clinical scholar, Liang is analyzing methods for management of rheumatic diseases.

One of the aims is to develop cost containment strategies for patients with such longterm illnesses. The computer databank, says Fries, provides for more accurate prognoses and more effective therapeutic programs as well.

Charles Irwin and members of the UCSF faculty have created a model treatment program for adolescents with learning problems as well as physical and emotional difficulties. Funded by the San Francisco Board of Education, the program is now in effect in five schools. Irwin has been appointed to the San Francisco Youth Guidance Center Medical Advisory Committee.

Lawrence Horowitz recently completed three years as a clinical scholar at Stanford, and has been appointed director of staff for the Senate Subcommittee on Health and Science chaired by Senator Edward Kennedy.

Horowitz worked with the subcommittee on questions of public participation in decisions on science policy, and also conducted a study on relationships between medical school activities and federal health objectives.

"This activity reflects concerns which lie at the heart of the reasons for the clinical scholars program," says Holman.

"It is a large and unusual task. Introducing nonbiological disciplines into medical thinking and practice will not by itself resolve the problems in health care...nonetheless these disciplines can yield understandings and methods which can greatly enrich and facilitate the search for better solutions."

The Robert Wood Johnson Foundation program is based on early pilot projects developed by Stanford and four other medical schools. In 1974 the Stanford program was integrated with UCSF and UC-Berkeley. "By combining the resources of our schools," says Holman, "we avoid duplication and provide greater breadth."

Five physicians have completed the training at Stanford; four have regular faculty positions, three of which are at Stanford. Three physicians completed the program at UCSF in June.

There are 10 programs nationwide. According to Dr. John C. Beck, director, the objectives include preparation of young physicians for careers in which they combine superior clinical skills with the ability to examine and think critically about medicine.

"Former scholars are in academic medicine, developing and managing health care institutions and delivery systems. They are also in a variety of public and private institutions involved in health-related public policy," says Beck. ### Mailed, Monday, June 20, 1977

STANFORD--Dr. David A. Rytand, Bloomfield Professor of Medicine emeritus at Stanford and chief of cardiology at Santa Clara Valley Medical Center in San Jose, is new president of the Stanford University Medical Alumni Association. New officers were named at the June meeting of the Board of Governors of the association.

Dr. Joseph W. St. Geme, Jr., professor and chairman of pediatrics at the Harbor General Hospital campus of the UCLA School of Medicine, was named president-elect.

Dr. Rytand, a member of the class of 1939, will serve as president through June 1978, succeeding Dr. Victor Richards of San Francisco.

Dr. Rytand, a specialist in renal and cardiovascular medicine, has been a member of the Stanford faculty for more than 35 years. From 1954 to 1960 he was executive head of the Department of Medicine. He has served several terms as secretary-treasurer of the Alumni Association.

President-elect Dr. St. Geme, Jr. has been associated with Harbor General Hospital since 1966. He had formerly been associate professor with the University of Minnesota Medical Center in the fields of pediatrics, microbiology, and laboratory medicine, and served as medical director of the diagnostic microbiology laboratory.

Dr. Don Goffinet, class of 1964, and assistant professor of radiology at Stanford, has been reelected secretary-treasurer of the medical alumni group.

New members of the Board of Governors are Dr. Lawrence S. Barnett, class of 1962, of Orange; Dr. Donald J. Prolo, class of 1961, of San Jose; and Dr. Ronald W. Thompson, class of 1965, of Los Angeles.

STANFORD--U. S. District Court in San Francisco has dismissed a suit filed by a former staff member at Stanford University School of Medicine who claimed she was discriminated against because of her sex.

Dr. Helene Rauch based her suit, which she asked the court to consider as a class action matter, on the university's decision not to appoint her to the medical faculty. She served as a research associate in Stanford's Department of Medical Microbiology from 1964 to 1975.

Rauch is now an associate professor of immunology and microbiology at Wayne State University in Detroit.

She was considered, but was turned down, by the department for a faculty appointment in 1970-71 and again in 1972.

U. S. District Court Judge William H. Orrick Jr. granted two motions filed by Stanford which agreed that the class action aspect of the Rauch suit be stricken, and that the suit be dismissed on summary judgment.

STANFORD--Community-based health education which relies heavily on the mass media can persuade people to change their life style and to improve their health status, according to a three-year Stanford University study.

Results of the study, which was funded by the National Heart, Lung and Blood Institute of the National Institutes of Health "strongly suggest that mass media campaigns directed at entire communities may be very effective in reducing the risk of cardiovascular disease."

The project is the first time that news media have been so extensively involved in a scientific behavior change effort at the community level.

Results are reported in the June issue of Lancet, a British scientific journal.

Dr. John W. Farquhar, director of the Stanford Heart Disease Prevention Program, says the project represents the type of preventive effort needed to help stem the epidemic of heart disease which claims the lives of more than 600,000 Americans per year.

"Most deaths of people under 65 in the U.S. due to coronary disease are preventable," he says. "We believe that success in achieving substantial behavior change at the community level lies at the root of any future national campaign to reduce premature mortality from heart disease and stroke."

The study began in 1972 with pre-campaign surveys conducted in three northern California communities--Watsonville, Gilroy and Tracy.

The researchers gathered data from about 500 randomly-selected men and women, aged 35 to 59, in each town. They measured knowledge about heart disease risk factors, daily intake of cholesterol, saturated and polyunsaturated fats, sugar and alcohol, and the daily rate of smoking. They also measured plasma cholesterol and triglyceride concentrations, blood pressure and body weight.

Two follow-up surveys took place at annual intervals. A random sample of residents in Tracy was surveyed each year as a control, but received no media campaign.

Fifteen percent of the Watsonville participant sample, at high risk for coronary heart disease, were selected for more intensive individual and group counseling in addition to the mass media campaign.

-more-

From 1972 through 1974, the mass media in Watsonville and Gilroy urged residents to change high risk habits such as cigarette smoking, to improve their diets, and to exercise. The campaign included more than 50 television spots, 100 radio spots, several hours of television and radio programming, newspaper advertisements and stories, billboards, posters, and printed material mailed to community residents. The campaign was conducted in both English and Spanish.

The researchers found that in the control community, Tracy, the risk of cardiovascular disease increased moderately over the two years. In the treatment communities, however, there was substantial and sustained decreases in cholesterol and triglyceride levels and in blood pressure; fewer respondents reported they smoked; and their knowledge about risk factors increased.

Compared to no treatment, overall risk of cardiovascular disease (heart attack and stroke risk) was reduced 25 percent in Watsonville and 24 percent in Gilroy after two years of the media campaign.

Compared with the control community, systolic blood pressure dropped 6 to 9 percent in the two towns.

In Watsonville, 32 percent of the intensively counseled high risk respondents had given up smoking by the end of the first year, and 44 percent had done so at the end of the second year.

This degree of change in smoking is, according to Dr. Farquhar, "unusually large; particularly since the change occured in a random sample rather than in the usual volunteers for smoking cessation clinics."

The combination of media and face-to-face intensive instruction of high risk subjects in Watsonville was more effective in altering smoking behavior than was mass media alone, according to the Lancet report.

The initial improvement was greater in this high risk group, but at the end of the second year the decrease in risk was similar in both treatment communities.

"The mass media," according to Dr. Farquhar, "are potentially much more cost-effective than face-to-face education methods. But we believe that media effects could be considerably enhanced if they could help stimulate and coordinate interpersonal instruction programs in natural community groups, such as towns and factories.

"We think our results to date already provide a basis for planning and carrying out community-based risk reduction," says Farquhar.

In future work, researchers hope to find ways to provide such instruction programs and longterm social support in the communities so as to help maintain the changes in life styles already initiated.

Farquhar, professor of medicine at Stanford's School of Medicine, heads the interdisciplinary research team. Dr. Nathan Maccoby, professor of communication, and Dr. Peter Wood, professor of medicine, are coprincipal investigators. ###

ADVANCE FOR RELEASE TUESDAY, JUNE 14, 1977

EDITORS: Release date of this story is set to coincide with Dr. Kalman's testimony at 9 a.m. Tuesday, June 14.

STANFORD--More evidence is needed before over-the-counter sedatives, sleep aids and stimulant drugs can be determined safe and effective, says a Stanford scientist.

A medical review panel of the Food and Drug Administration found that none of the daytime sedatives or nighttime sleep aids on the market can be judged safe on the basis of available evidence, according to Dr. Sumner Kalman, professor of pharmacology at Stanford Medical School, and member of the panel.

Kalman discussed the panel's findings in testimony prepared for the Senate Select Committee on Small Business on Tuesday, June 14.

He said that bromides, considered a serious health hazard, and belladonna alkaloids, currently subject to abuse as street drugs, should not be marketed for casual use as sleep aids.

There is little evidence, he said, that antihistamines are effective sleep aids in the doses currently available. The panel placed those drugs in the category as requiring more evidence before the scientists could make a decision about their effectiveness and safety.

Only one drug, caffeine, appeared to be safe and effective as a central nervous stimulant that would restore attention and wakefulness in a tired person, he said. The drug will not, however, confer ability greater than the person normally has, he pointed out.

According to Kalman, the panel had difficulty in determining whether daytime sedatives helped relieve anxiety or simple nervous tension.

"We were not at all sure that there was demonstrable benefit from the use of these drugs. The only controlled studies that we saw showed no benefit of these substances over a placebo."

The Stanford scientist felt that daytime sedatives should be removed from the market, but the majority of the panel voted to give manufacturers the opportunity to do additional studies.

In his testimony, he noted "I think that if a suspicion exists about the ineffectiveness or the lack of safety of a drug or of both, it should be withdrawn." If marketing and advertising cannot be stopped, he says, then advertising claims about safety or effectiveness should not go beyond those found by the panel which reviewed it.

The casual use of drugs should be discouraged, he says. "Many of the indications for drug use are trivial ones, and most drugs are so poorly understood that we may, by taking them for the relief of transient discomfort, subject the body to severe poisoning which may not be manifest for a long time."

Persons should consider the possibility that they may not need drugs for trivial symptoms, he said. "Occasional nervousness or anxiety is a normal part of living and does no harm. . . . Occasional sleeplessness is a normal response to extra pressures."

STANFORD--Stanford University School of Medicine awarded 169 degrees during its annual commencement exercises Sunday, June 12.

The ceremonies also honored seven medical school faculty members for outstanding achievements in teaching.

Medical degrees were presented to 107 men and women. The medical school also awarded 17 Ph.D's, 38 masters' and seven bachelor of science degrees.

The diplomas were presented during ceremonies in Stanford Medical School's Grant Courtyard following the university's 86th annual commencement rites at Frost Memorial Amphitheater.

Dr. Clayton Rich, vice president for medical affairs and dean of Stanford Medical School, and Dr. Roy Maffly, professor of medicine (nephrology), presented the diplomas.

Dr. Elisabeth Kubler-Ross, psychiatrist, author and widely-recognized authority on care of the dying, presented the guest address.

Maffly was singled out by the medical students for two teaching awards. The students voted him as recipient of the Arthur L. Bloomfield Award for recognition of excellence in teaching of clinical medicine, and the Henry J. Kaiser Award for excellence in teaching.

Four other faculty members were also selected by the students for Kaiser teaching awards, including Dr. Michael Jacobs, assistant professor of ambulatory medicine, who was named for the second straight year. Also selected were Drs. Gerald Levine, assistant professor of pathology; Norman Blank, professor of radiology; and William Watson, assistant professor of dermatology.

The Henry J. Kaiser Awards for outstanding and innovative contributions to medical education were presented by Dean Rich to Drs. Duncan Govan, professor of surgery (urology) and Jon Kosek, professor of clinical pathology.

Lucille Daniels, emeritus professor of physical therapy, was named recipient of the first Lucille Daniels Recognition Award for Outstanding Contributions to Physical Therapy. The award will be given annually. ### Mailed Monday, June 13, 1977

STANFORD--Dr. Tag Eldin Mansour has been appointed chairman of the Department of Pharmacology at Stanford University School of Medicine.

His appointment was announced by Dr. Clayton Rich, vice president for medical affairs and dean of the medical school.

Mansour, a professor of pharmacology, has served as acting department chairman since the fall of 1976, following the resignation of Dr. Lewis Aronow.

A member of the Stanford medical faculty since 1961, Mansour has concentrated his research into three general problems within the field of cell regulation and the effect of drugs on cellular control mechanisms.

He received a doctor of science degree in biochemistry from the University of Birmingham, England, for his research on phosphofructokinase, an enzyme crucial in sugar metabolism of the heart.

Mansour earned his bachelor of veterinary science, medicine and surgery degree from the College of Veterinary Medicine at the University of Cairo, Egypt. He studied physiology and pharmacology at Edinburgh University in Scotland and in 1949 he earned a Ph.D. in pharmacology from Birmingham University Medical School in England.

In 1952-54 Mansour was a senior instructor and research associate in the Department of Pharmacology at Western Reserve University Medical School in Cleveland, Ohio, and during 1955-61 he was on the medical faculty in the Pharmacology Department at Louisiana State Medical School in New Orleans.

Mansour presently serves on the editorial boards of Biochemical Pharmacology and Archives Internationales de Pharmacdynamie et de Therapie.

He is a member of the American Society for Pharmacology and Experimental Therapeutics, the American Society of Biological Chemists and a fellow of the American Association for the Advancement of Science. He served as an adviser to several national and international health organizations.

FOR IMMEDIATE RELEASE

STANFORD –

Paul B. Hofmann, director of Stanford University Hospital and Clinics, has announced the departure of associate directors John A. Kneepkens and Howard J. Wooling.

Kneepkens has requested early retirement while Wooling will be accepting another position elsewhere, Hofmann said.

Kneepkens is an associate director of the Hospital and Clinics having responsibility for the Clinics, Reservations, Rooming and Information, Social Services, and Patient Placement Services. In addition, he has had responsibility for emergency services and the operating rooms.

Previously, Kneepkens served as business manager for the Department of Surgery at Stanford Medical School.

Before coming to Stanford in 1967, he served with the U.S. Army on the faculty of the Command and General Staff College at Ft. Leavenworth, Kansas. He holds a B.A. degree from San Jose State.

Wooling has been at Stanford since 1972 and has served as associate director since 1974. His duties have covered many of the Hospital's services, including EEG, drug assay, and EMG laboratories, dietary, immunology, infection control, infectious disease laboratory, medical records, clinical labs, coagulation, pathology, radiology, virology lab, transfusion, cardiology, and chaplaincy service.

Wooling previously served as assistant director of the Hospital. He holds a master's degree in public health from the University of California at Berkeley, another master's from Boston College, and a B.A. degree from Eastern Nazarene College.

STANFORD--Stanford University School of Medicine will begin a review to revise its medical service plan, Dr. Clayton Rich, vice president for medical affairs and dean of the School, announced Wednesday.

At the same time, Rich said he was advised by Dr. Norman E. Shumway, chairman and professor of the Department of Cardiovascular Surgery, that he will resume billing patients for professional services.

A story in the Palo Alto Times Monday reported that Shumway and his associates had discontinued billing patients because of their concerns over certain aspects of the medical service plan, including the possibility that the plan may be in conflict with state law.

Dean Rich said the university remains confident that the present medical service plan is in conformity with state law.

He said the chairmen of the clinical departments, including Dr. Shumway, will begin meeting regularly to review and make appropriate revisions to the existing plan relating to the method of allocating funds received by the university which are subject to the plan.

Dr. Rich said the plan was last revised in 1974 with the expectation that it would be reviewed again in 1977.

He said the proposed revision may be completed in about three months.

STANFORD--A total of 140 scientists, six from Stanford University, have signed a statement calling pending legislation on recombinant DNA research "unwarranted and imprudent."

The scientists urge Congress to avoid unnecessary legislation that could deny society of needed improvements in public health, agriculture, industry and environmental protection.

The statement emerged from a recent conference on biological regulatory mechanisms held in New Hampshire. Among the Stanford signers are Professors Ronald Davis, Dale A. Kaiser and Charles Yanofsky, and George Bennett, Frank Lee and Richard Lifton.

"We believe that the bills presently before Congress would impose unjustifiable controls over many important areas of scientific inquiry," the statement said.

Two bills presently before each house would make guidelines, issued by the National Institute of Health, binding throughout the United States and would provide serious penalties for violations.

A basic difference between the two bills is that the version sponsored by Senator Edward M. Kennedy (D-Massachusetts) calls for a national commission, with its chairman appointed by the President, to regulate and monitor all recombinant DNA research in the United States.

The second bill sponsored by Rep. Paul G. Rogers (D-Florida) would give the regulatory task to a special advisory committee under the secretary of Health, Education and Welfare.

Both bills would preempt state or local laws limiting recombinant DNA research.

The field of recombinant DNA research or gene splicing has been controversial for several years because of fears that organisms and viruses created by the research may spread quickly and without warning to persons, agricultural plants and products.

"The premise on which these bills are based derives from exaggerations of hypothetical hazards that go far beyond reasoned assessment," the scientists said.

"The experience of the last four years is important. Despite a vigorous search to identify the degree and nature of any actual public health or environmental hazard, no indication of actual danger has been uncovered. Many conjectured dangers have been shown not to exist.

"It is evident that dramatic advances in fundamental knowledge have already emerged from the application of these techniques.

"We are concerned that the legislative measures will set up a bureaucratic machinery so inflexible and unwieldy as to severely inhibit the development of many fields of knowledge."

The statement said it would be unwise to legislate against hazards which do not exist and shown to be improbable.

STANFORD –

The 21 Northern Californians who finished Stanford University Hospital's paramedic training program this week bring to 150 the number of persons who have completed the program since it began in 1973.

All of the recent graduates are members of fire departments or ambulance companies, except for one graduate who works for the National Park Service in Yosemite.

The paramedic trainees received over 200 hours of lecture and 300 hours of clinical work from Stanford physicians and nurses.

The graduates received diplomas during ceremonies Thursday, July 21, in Sherman Fairchild Auditorium at Stanford Medical Center. Each has been recommended for certification as a paramedic in his or her individual county.

Graduates include Paul Buenrostro, Robert Davidson, and Mike Maier, Palo Alto Ambulance Company; Vi Croop, Jerry Hamm, Susan Jackson, John Rowles, Vince Schweitzer, and Gerry Wood, Medevac of San Mateo; Gene Gantt and Lynn Norman, Vacaville Fire Department; Paul Gantt, Pomeroy Ambulance Company of Walnut Creek; and Mark Sgambati, San Jose Ambulance Company.

Also, Jack Goode, Bob Makjavich, Chris Shinseki, and Bob Wall, Palo Alto Fire Department; Terry Gritton and Greg Joseph, Aptos Fire Department; Ron McCluskey, Solano Ambulance Company of Vallejo; and Mead Hargis, National Park Service at Yosemite National Park.

STANFORD--Elections to determine whether employees at Stanford University Hospital and Clinics prefer union representation for collective bargaining will be held once again, this time on Feb. 2-4, 1978, according to a settlement agreement reached by Stanford and a Stanford employee union.

The National Labor Relations Board (NLRB) approved the elections agreed upon by the university and United Stanford Employees (USE), Local 680, Service Employees International Union, AFL-CIO. The settlement agreement was reached prior to a hearing on the matter before an NLRB administrative law judge in San Francisco.

The settlement sets aside only those results of previous secret ballot elections in which USE participated. In the elections, held two years ago and conducted by the NLRB, more than 1,000 of 1,200 eligible employees overwhelmingly rejected any union representation.

The new elections are the result of an unfair labor practice complaint and election objections filed by USE against the hospital and the university, alleging that two minority employee groups--La Alianza Latina and the Black Advisory Committee--were unlawfully assisted and directed by the hospital. Both employee groups have been active in affirmative action efforts.

USE said the assistance included time off to attend meetings, the use of meeting rooms, a budget covering materials and supplies, and occasional advice by certain administrators.

Charges of unfair labor practices were filed by USE in connection with the election, held April 10-12, 1975.

In a letter mailed to Stanford Hospital and Clinics employees last week informing them of the new election, director Paul B. Hofmann also described legal proceedings prior to and following the first elections.

He noted that USE had attempted to have the NLRB call off the original elections the day before they were to take place. The NLRB refused.

Hofmann further noted that USE had filed objections after the election asking that they be rerun, but that none of the other participating unions had filed objections.

In his letter, which was written in English and Spanish, Hofmann said the NLRB also rejected a USE complaint that the medical center "had dominated" La Alianza Latina and the Black Advisory Committee that directed their pre-election campaign against USE.

-more-

"Both the hospital and the university have always considered the most important issue in this matter to be their right to continue to communicate with employees, including minority and women's groups," Hofmann said.

In addition to USE, other groups that were rejected in the 1975 election were the Stanford University Housestaff Association, Stanford United Medical Technologists, and the California Licensed Vocational Nurses Association.

A fifth union, the Stanford University Medical Center Engineering Association, withdrew prior to the election.

###

STANFORD--Roland S. Merchant has been appointed as a special assistant to Peter J. Levin, associate vice-president for medical affairs at Stanford University Medical Center.

Merchant recently served as assistant administrator and acting administrator at West Adams Community Hospital in Los Angeles.

He previously was the director of health and hospital management in the City of New York's Department of Health, and in the administration at Roosevelt Hospital in New York.

Merchant, who holds masters' degrees from Columbia, is a member of the American Hospital Association, New York Academy of Sciences, and American Public Health Association.

STANFORD--Two Stanford University Hospital security guards and a supervisor were treated for minor injuries in the emergency room early Friday morning following an incident with employees in the hospital's east wing.

The incident took place at 1:30 a.m. as the night shift of housekeeping employees was getting off enroute to the parking lot.

The guards, Don E. McQuillis and Jerald Ingersoll, and hospital security supervisor, George F. Whitfield had asked one of the employees carrying a tape player to turn the music down because it was disturbing the patients.

According to the incident report, McQuillis was struck in the jaw by one of the employees. A fracas ensued and Palo Alto police were called in. There were no arrests.

The guards, employees of Sentry Security Service, have filed personal assault and battery charges against two suspects.

Hospital officials said this morning they are investigating the incident.

FOR RELEASE WEDNESDAY, July 13, PM PAPERS.

Editors: Release date for this story is set to coincide with presentations from the Lipid Research Clinics Program of the National Heart, Lung, and Blood Institute, to be made on Wednesday, July 13, at the National Institutes of Health, Bethesda, Maryland. Nationwide data will be presented at that meeting; this story concerns data collected from a study of 4,300 Stanford University faculty and staff.

STANFORD--Considerably more women employees at Stanford over age 25 smoke cigarettes than men of the same age.

--Risk factors for heart disease appear to be more common among individuals with less formal education than among college graduates.

--On the average, Black employees smoke more than other racial groups, have higher blood pressures, but lower blood lipids (fats).

--Women employees may have lower cholesterol levels than men up to age 45, but after that their cholesterol levels average higher than men.

These are some of the preliminary findings from a study of 4,300 Stanford University faculty and staff initiated four years ago to evaluate their risks for developing heart disease.

The screening project is part of the Stanford Heart Disease Prevention Program, and funded by the Lipid Research Clinics Program of the National Heart, Lung and Blood Institute. Fifteen clinics located in the U.S., Canada, Russia and Israel are gathering similar data in a collaborative effort to determine the frequency of selected heart disease risk factors in various populations.

Dr. William Haskell, Stanford physiologist with the program, reported that three out of four eligible Stanford employees participated. Approximately 5,900 employees 26 years of age or older were eligible.

For most employees the screening consisted of a 15-minute health evaluation, including a brief medical questionnaire, height, weight and blood pressure measurements, plus cholesterol and triglyceride analysis of a blood sample.

Almost 1200 of these employees returned for a second, more extensive evaluation, including a brief cardiovascular examination by a physician, an electrocardiogram recorded at rest and during treadmill exercise, and more extensive blood chemistry tests.

Results of both examinations were made available to the participants and on request to their physicians.

-more-

All employees over age 30 who participated in 1973-75 will be recontacted again beginning in September 1977 to determine changes in their health status. Future surveys may be conducted at several year intervals.

One of the most surprising findings of the Stanford survey, says Haskell, is that 35 percent of women in the study smoke cigarettes compared to 22 percent of men. "This seems to reflect the national downward trend in cigarette smoking by men, and the upward trend for women," says Haskell.

He also reported the frequency of smoking was closely related to the person's level of education. For example, among male college graduates only 18 percent smoked, compared to 36 percent among high school graduates.

Generally, risk factor levels tended to be higher among the less educated. In the Stanford study, college graduates tended to be leaner, have lower blood pressures, lower blood fats, and smoke less than age-matched individuals with less education. These differences exist for both men and women.

However, the Stanford study revealed that levels of risk factors were the same wherever people work, at SLAC, the School of Engineering, Humanities and Science, or the Medical School. "Despite their proximity to health services, employees of the Medical School fared no better than the rest of the University," says Haskell.

According to the data, 50 percent of participating Black employees smoke, compared with 30 percent of all other groups. Among men, Blacks tend to have higher blood pressures but lower blood lipid levels, especially triglycerides.

Haskell noted that diet programs for heart health should be directed not only toward men, but women as well, since after age 45 women had even higher cholesterol levels than the men.

"We also measured a definite blood fat elevating effect with synthetic harmones," says Haskell. One-third of the women participants reported they take oral contraceptives or synthetic estrogens for other purposes.

"In the 25 to 45 age group, triglyceride levels are substantially elevated while there are modest elevations in cholesterol in women using oral contraceptives," he says.

This was also a finding at the other centers. The medical significance of elevated blood fats associated with the use of oral contraceptives has not been established, according to Haskell.

He cites the "tremendous cooperation" the study received in the Stanford community. Because of the large number of participants additional studies are being conducted or planned for the future. For example, one study started last fall involves evaluation of women prior to their use of oral contraceptives, and of changes in their risk factors after they begin using the pill.

-more-

The immediate families of 200 persons from the initial study also were screened for their risk characteristics. Parents, spouses, siblings, if they lived anywhere in North America, were asked to answer questionnaires and have blood lipid tests.

An average of seven persons per family are being screened, for a total of about 1400 individuals. Other cooperative centers are also studying the relationship between genetic and environmental factors in heart disease.

In addition, about 300 persons from the first study were invited back for evaluation of heart function using ultrasound, or echocardiography. This is a harmless and painless method of using radar-like echo soundings to determine the size and movement of specific heart structures during various phases of the heart cycle.

Some employees were identified as high risk candidates for heart disease, although they were totally unaware of it, says Haskell. As a result of survey findings, medical treatment could be started. For example, a 24-hour ambulatory electrocardiogram is performed on those found to have atypical heart rhythms during treadmill exercise tests.

According to Haskell, "one of the biggest benefits of the survey to participants has been the discovery of high blood pressure in many individuals who were not aware they had this problem."

The aim of this longterm study, says Haskell, is to establish normal values for characteristics associated with the risk of heart and blood vessel disease for the different sexes, ages, and ethnic groups, and to determine the frequency of certain abnormalities in lipid metabolism.

"As the result of longterm follow-up of participants at each center, a better understanding of which environmental factors are most closely related to heart disease risk can be established for men and women of all ages," says Haskell. Data then will be available to formulate strategies for more effective heart disease prevention programs in the future, he says.

STANFORD--Although computers are used increasingly to predict patients' medical outcomes, such as recovery from coma, a Stanford researcher says their predictions may not be better than those of a good clinician.

Dr. Alan Shapiro has suggested a new way to analyze how doctors and computers predict medical outcomes.

Previous studies have generally claimed that computer performance is often comparable to that of clinicians. But Shapiro, in the Department of Medicine at Stanford and a Robert Wood Johnson Clinical Scholar, found that no computer program did as well as experienced clinicians when analyzed by his method.

It should not be surprising, he writes in a recent issue of The New England Journal of Medicine, that computers do not outperform a physician "who can use many variables, can take correlation of symptoms into account, and most important can adjust to the context of a particular patient's illness."

But a good computer predictor, he says, might also be worthwhile in assisting physicians in their judgments.

In a study with 20 Bay Area rheumatologists, Stanford faculty, fellows, and students, Shapiro presented a patient's case history, clinical history and laboratory results. He asked each participant for their judgments about how the patient would fare: death in one year, kidney failure, and other outcomes.

After the doctors answered the questions, they were told what a computer predicted for the same patient. They were allowed to change their answers if they wished, using the computer as they would an outside consultant.

Shapiro found that the computer did only average in its predictions.

But the physicians who had initially done worse than the computer, did better after consulting with it.

"Accurate prediction of outcomes is an essential skill in medical practice, and has been neglected as an object of study," he says. He feels that better analyses of doctors' predictive ability could be applied in evaluating new aids to physicians.

-more-

222--Medical Predictions

Traditionally, the most widely used method of evaluation is to look at a physician's "error rate." If the physician predicts that a patient will be cured by surgery and the patient is not cured, then the doctor has, in retrospect, made an error. The proportion of such errors is the error rate.

The error rate is a very insensitive measure, according to Shapiro. It does not take into account the magnitude of mistake. "Decisions can be considered right or wrong; probabilities are never right or wrong but are best considered as more or less accurate," he explains.

A decision is made up of a number of separate predictions, such as potential relief of symptoms, adverse reactions, or other individualized outcomes.

Using Shapiro's method, the doctor who assigns the highest probability to what actually happens receives the highest score. The method offers a graded means of evaluating a physician, in contrast to the right-or-wrong measure used traditionally.

When the method was tested on physicians and students at Stanford, Shapiro found that, in general, predictive skill was closely related to level of training. Faculty scored higher than fellows, who scored higher than residents, who in turn outscored students.

According to Shapiro, a physician may make an inaccurate prediction because of incorrect information, or because he failed to adapt that information to the unique characteristics of his patient.

"Effective individualization of predictions requires consideration of the social and psychological as well as biological characteristics of a patient," he says.

Shapiro says his method can analyze how well a physician performs in both aspects.

The same approach can be applied in assessing the value of diagnostic test results to a doctor. "A physician who abandons his clinical judgment in deference to the results of a new test that he understands only imperfectly may suffer a decrease in predictive accuracy," says the researcher.

Shapiro's work is supported by a grant from the National Center for Health Services Research to the American Rheumatism Association Medical Information System.

STANFORD--Dr. George H. Houck, professor of medicine emeritus who helped establish the Stanford Student Health Service, died Tuesday, July 5, of a heart attack. He was 75.

Dr. Houck came to Stanford in 1946 with Dr. John Eckert, now a retired local physician, to begin a student health service.

A brain child of Dr. Russel V. Lee, the service made Palo Alto Clinic physicians available to Stanford students on a contract basis and was considered a unique medical development at the time.

Dr. Houck was born in Roseburg, Oregon. He attended the University of Oregon, graduating in 1923, and Harvard Medical School where he received the M.D. degree in 1927.

In the summer of 1926, he worked with Dr. Paul Dudley White, the noted heart specialist and presidential physician, and interned at Peter Bent Brigham Hospital in Boston from 1927-29.

Dr. Houck received his residency training at Stanford Hospital in San Francisco under the famed Dr. Arthur Bloomfield.

In 1931 he entered the practice of medicine in Los Angeles. During World War II he served in the Army Air Medical Corps as a colonel, and he remained active as a reservist for many years.

Dr. Houck retired in 1967. During his active career he was a member of the Palo Alto Medical Clinic staff as well as a member of the Stanford medical faculty.

For the past year, Dr. and Mrs. Houck lived in Channing House in Palo Alto. His wife, Flora, is a pediatrician, and a graduate of the University of Oregon.

Dr. Houck was a member of the Palo Alto Club and of the Palo Alto Rotary Club.

His medical affiliations included the Santa Clara County Medical Society, the Los Angeles Academy of Medicine, and the California Academy of Medicine. In 1939 he served as president of the Los Angeles Heart Association.

Besides his widow, Dr. Houck is survived by two children, a daughter, Mrs. John (Janet) Boretta, of Orinda, and a son, George, of Olympia, Washington.

No funeral services are planned. The family suggests that memorial gifts be made to the Palo Alto Medical Research Foundation.

STANFORD –

Stanford heart surgeons hope to increase the number of donor hearts available for transplants by using a technique for transporting hearts outside of the body.

The technique enables them to fly hearts from as far away as Los Angeles. Three hearts have been flown this way since 1973, one from Los Angeles and the others from Oakland and Marin County.

Hearts are transported under a new cooperative arrangement with the Regional Organ Procurement Agency for Southern California. The agency, based at University of California at Los Angeles, also provides organs for kidney and liver transplant programs in California, Nevada, and Colorado.

"The program gives us access to a greater number of donor hearts than we've ever had before," says Lois Christopherson, chief social worker in the Department of Surgery.

Christopherson hopes the program will find donor hearts more quickly for recipients. An average of one out of four potential recipients dies before an appropriate donor heart becomes available, she says.

"This year we had several patients die while waiting." Presently three patients at Stanford are waiting for hearts, she says.

According to Dr. Eugene Dong, Jr., a member of the Stanford transplant team, donor and recipient hearts are matched on the basis of blood and tissue types. This information can be relayed by phone when the donor and recipient are in different locations, he says.

The major difficulty with the transport technique, says Dong, is that the heart is without a blood supply during transport.

Usually the heart is transplanted directly from the donor to the recipient. When the body of a donor is transported to Stanford, says Dr. Bill Baumgartner, chief resident in cardiovascular surgery, the blood flow through the heart is maintained almost continously.

"The heart is beating up to the second it is removed," he says. "Within 45 minutes it is reconnected in the recipient."

When the heart is transported out of the body, it may be without blood supply for as long as three hours. To keep it in healthy condition for the transplant, the heart is flushed with and stored in an electrolyte solution, then cooled to near freezing.

The technique slows down the metabolic activity of the heart and preserves it during transport, says Baumgartner.

Transported hearts have been doing fine after transplantation, he says.

To what distances doctors can travel for donor hearts depends on how long they can remain viable outside the body. This time period is still unknown for human hearts.

"In animal experiments," says Baumgartner, "the cooled heart will remain viable for transplant up to 24 hours. But we're putting a four-hour limit on human hearts."

The Las Vegas vicinity is one of the farthest areas Stanford surgeons will travel for the organ. The kidney procurement program in Las Vegas can also obtain donor hearts.

According to Christopherson, the ability to transport hearts outside the body will take some of the pressure off donor families. "Sometimes families are more comfortable if a specific organ is transported rather than the whole body," she says.

Stanford performed its 128th heart transplant in late August. Fifty-one recipients are still alive. The longest survivor, a 48-year-old man from Mill Valley, received his heart in January 1970.

FOR IMMEDIATE RELEASE

STANFORD –

Dr. Harold Christian Zweng, internationally renowned ophthalmologist and pioneer in the treatment of eye diseases with the laser, died Friday, August 26, at Stanford University Hospital of complications due to a stroke. He was 54.

Memorial services will be held Tuesday, August 30, at 10 a.m. in Stanford Memorial Church. Friends are welcome to attend.

Zweng and his associates began developing a ruby laser photocoagulator in 1962, treating the first patient a year later. While thousands of patients were treated with the instrument during the next 10 years, Zweng pioneered in developing an argon laser.

The argon laser has been one of the most effective methods of treating diabetic retinopathy, a disorder of the blood vessels of the retina. In 1970 a commercial version of the prototype instrument was developed, and more than 600 such photocoagulators are now in use for patient care around the world.

Zweng was clinical professor of surgery (ophthalmology) at Stanford University Medical School. Since 1971 he and his associates have conducted courses to introduce the techniques of laser photocoagulation to physicians throughout the U.S. and in other countries.

He authored two books and more than 70 articles on laser photocoagulation.

A graduate of Stanford University (1945) and Stanford School of Medicine (1949), he was a veteran of both World War II and the Korean War.

Zweng practiced at the Palo Alto Medical Clinic from 1954 to 1975, and was a member of its executive board from 1969 to 1974.

In 1975 he joined two other Clinic retinal specialists and formed the Palo Alto Retinal Group, in which he practiced actively until his illness. He was also instrumental in founding the Palo Alto Retinal Research Foundation.

He was elected to the Palo Alto City Council in 1959 and served until 1965. He was chairman of a fund-raising effort to establish Foothill Junior College, and was made honorary trustee in 1958.

He was trustee of the Palo Alto Medical Research Foundation from 1965 until his death.

He is survived by his wife, Jean, and children Joe, Nancy, Tom, Paul, Carol, and Peter.

STANFORD –

Cost cuts applied 'across the board' to all medical services won't help solve the nation's major cost problems, says a Stanford physician.

Cost reductions can be achieved by such methods, but the quality of care is not likely to be improved, says Dr. James F. Fries, assistant professor of medicine at Stanford University School of Medicine, and coauthor of a popular consumer's guide to medical care.

Such administrative responses as "putting a lid on costs," says Fries, only perpetuate maldistributions by impacting all services equally.

He calls instead for more efficient medical care. "The bulk of unproductive efforts probably occur in rather ordinary medical settings," he says.

"Unfortunately, with finite limits, resource allocations and human lives are part of the same equation," he writes in the current issue of *Stanford MD,* journal of the Stanford Medical Alumni Association.

"Expenditures for penicillin shots for colds could have been used instead to educate for physical fitness and habit moderation. . .costs of hospitalizations for tests could have been an investment in basic medical knowledge for the next century."

According to Fries, the major cost problems come from what he calls 'physician-generated' costs. The physician is the one who decides who will be hospitalized and for how long, which tests will be performed, and what treatments will be given.

But Fries believes that both physician cost-generating behavior and patient behavior can change.

No differences in patient outcomes have been established, he says, for physicians who generated greater or lesser amounts of laboratory tests or X rays for their patients.

In one study, when the differences in costs were presented to doctors, there was a shift of physicians who generated high costs toward the mean or even below it.

"In one clinic paying particular attention to laboratory and drug use over a five-year period, costs decreased by one-third while outcome in the specific disease studied improved."

In his article, Fries cites several examples of new medical approaches that not only saved money, but improved care to patients, without coercion or regulation. These include the decrease from three drugs to two for standard antituberculosis therapy, when it was shown that patient outcome was just as good with fewer drugs.

Elaborate evaluations of the hypertensive patient have been simplified, he says, as a result of identifying factors relevant to patient outcome.

And screening programs for diabetes and the use of oral hypoglycemic drugs were reduced after studies suggested no benefit or even harm from them.

In the effort to improve the national health outcome, he calls for more investigation in subjects like economics, sociology, and other social sciences, pharmacology, physiology and traditional clinical research techniques.

Fries, coauthor of the consumers guide, *Take Care of Yourself,* says "the health delivery system in a finite world cannot be humane unless it is efficient."

FOR IMMEDIATE RELEASE
STANFORD –

There is a pressing need to improve the treatment of serious injury, according to Dr. John Collins, professor and chairman of the Department of Surgery at Stanford University School of Medicine.

"The number of people suffering from a major injury in the United States continues to be appallingly high," he says. "Many of the complications occurring after serious injury are a result of how the patient is taken care of initially."

Collins, 43, is well known for his work on traumatic shock and blood replacement. Before his appointment to the Medical Center in April he was professor of surgery at Washington University in St. Louis.

Collins began studying how the body responds to severe injury as a captain in the U.S. Army Medical Corps in Vietnam. He organized the first Army surgical research team, sent there in 1966.

Studies of combat casualties conducted by the team made important contributions to present knowledge of resuscitation and blood transfusion.

For instance, the researchers found that the lungs of injured soldiers were bearing the brunt of many of the posttraumatic complications, including build up of fluids. The complications resulted from the injuries in part, but also from the way fluids were used for resuscitation.

Greater caution in the use of fluids has helped to reduce pulmonary complications in serious injuries over the last 10 years.

Collins also found that the body, even when seriously injured, can neutralize the increased acidity of stored blood which is given as a transfusion. Administration of a neutralizing solution to protect against acidosis is not necessary and may be detrimental.

Collins says that the military provided an excellent emergency system of transportation and treatment which helped reduce the number of lives lost during the war.

"On-the-spot treatment by well trained young men who were not physicians but who knew how to treat injuries well in the initial phase was backed up by a very well-organized system of transportation and communication," he says.

"It was an old saw over there that you had a better chance of surviving if you were wounded in the middle of a jungle in Southeast Asia than if you were hit by a taxi in Manhattan."

The same quality of care can be provided in a civilian setting, he says, where there are a good paramedic training program, a unified communications system, and some degree of regionalization among health centers.

Collins plans to continue his research on transfusions and the complications of blood loss, in addition to his administrative duties at Stanford.

As head of the Department he is responsible for the quality of patient care, education of medical students, and research in several divisions of medicine, including neurosurgery, ophthalmology, orthopedics, otolaryngology, plastic and reconstructive surgery, and urology.

One of his current concerns is the need for more space both in Hospital and Medical School surgical facilities. "The expanded intensive care facilities are helpful," he says, "but we are very seriously in need of additional operating rooms."

Collins would like to increase the research involvement of the Department in areas such as immunology and infectious diseases.

"I'd like to get Stanford into renal transplantation," he says. "Not only is it an important patient service, but it is a clinical subject that this institution should be involved in."

"The opportunities for productive research at Stanford are very great," says Collins. "The basic science departments in the Medical School and the University are superb. And the system has excellent clinicians, providing first-rate care to patients."

STANFORD--Dr. Cicely Saunders, founder of the modern-day hospice program in England, will speak on various aspects of terminal care Thursday, Aug. 25, at Stanford University Medical School.

Her address, sponsored by the Department of Family, Community and Preventive Medicine, begins at 10 a.m. in Room M-106. It is open to the public.

A former nurse and social worker, Dr. Saunders received her medical degree in 1957.

From 1958 to 1965 she worked at St. Joseph's Hospice in London and laid the foundations for the care of terminally ill patients. She is the founder of St. Christopher's Hospice, whose concepts have been emulated by institutions for terminal care in the U.S. and the United Kingdom.

Hospice is a term revived from the Middle Ages which refers to facilities that provide spiritual, emotional and physical support for the sick and dying.

Dr. Saunders has authored articles on the care of the dying. Earlier this year she was awarded a Lambeth Doctorate of Medicine from the Archbishop of Canterbury, Frederick Donald Coggan. She also holds an honorary doctorate degree from Yale.

STANFORD--Pottery, paintings and photography will be among the art work on display August 22 through 26 at the Stanford University Medical Center Art Show.

The show will be held in the Sherman Fairchild Auditorium lobby, and is open to the public. Hours are Monday, Wednesday and Friday from 7 a.m. to 3:30 p.m. and Tuesday and Thursday from 9 a.m. to 5:30 p.m.

Faculty and staff members of the Medical Center have submitted more than 100 entries in categories of painting, sculpture, pottery, photography, stitchery, jewelry and glasswork.

First, second and third place ribbons in each category will be presented by a team of judges.

Among the entries are welded copper and bronze sculpture, several manzanita burl carvings, papier mache sculptures and stained glass.

The show was a popular annual event several years ago, and is now being revived.

Those attending will be able to cast votes for the one entry they consider the "best of the show." This award will be presented on Thursday, August 25, at 5 p.m. by Stanford Hospital Director Paul Hofmann.

FOR IMMEDIATE RELEASE

STANFORD –

Stanford University Hospital charges will increase an average of 8.5 percent in the new fiscal year starting September 1.

The new rates, according to Paul Hofmann, director of the Hospital and Clinics, reflect increases in wages and benefits, utilities, malpractice insurance, and other costs such as medical supplies. He noted that this is the lowest price increase for the Hospital in recent years.

Rates were approved by the University after the Hospital Board of Directors reviewed the annual budget on Tuesday, August 16, recommending rates for the new fiscal year.

Medical and surgical room rates, which are charged to most hospitalized patients, will increase approximately 7.5 percent from those set one year ago.

The new rates will be $144 per day for ward accommodations, $157 for a semiprivate room, and $177 for a private room.

Medical and surgical patients utilizing the services of house staff physicians will pay $14 more than the above rates. The patient's attending physician determines whether such services are utilized.

Based upon related costs, the level of rate increases will be higher for specialized units, such as the intensive and coronary care units, psychiatry, and the nurseries.

Rates for X-ray, laboratory, and other ancillary services, which represent about one-half of all charges to patients, will be increased selectively, averaging about 7 percent.

"We are well aware of nationwide concern about hospital costs," Hofmann noted, "and we are pleased to be able to report that in our own institution the rate of increase in costs is being slowed."

He pointed out that the new rates compared favorably with those charged by similar highly specialized teaching facilities.

More than 98 percent of the hospital's funds, he said, come from patient revenues. The hospital has no tax support or endowment income.

FOR IMMEDIATE RELEASE
STANFORD –

In order to make significant advances in the treatment of leukemia, "we need new concepts, ideas, and research to build on," says Dr. Joseph V. Simone, new director of pediatric oncology and hospital physician-in-chief at Children's Hospital at Stanford. Simone's appointment became effective August 1.

Simone, 41, came to Children's Hospital from St. Jude Children's Research Hospital in Memphis, Tennessee, where he gained prominence for his work in childhood leukemia. During the 10 years he spent at St. Jude he served as chief of hematology and chief of hematology-oncology.

According to Dr. Irving Schulman, chairman of the Department of Pediatrics at Stanford University School of Medicine, "Dr. Simone is universally regarded as one of the true leaders in the field of pediatric hematology in this country."

Progress in the treatment of the disease over the last 10 years, says Simone, has increased the chances of 8-year leukemia-free survival from less than 1 percent to 50 percent.

But despite improvement in the chances for survival, "there have been no significant advances in the treatment of leukemia over the past several years," he says. There is a need for more research, and that, for Simone, is the challenge he'd like to help Children's Hospital meet.

Simone has been on the job less than two weeks, but already he is brimming with ideas for the Hospital. A major effort during the next few months, he says, will be made to organize the oncology services so that optimum patient care, education for medical students and residents, and research are provided as efficiently and productively as possible.

According to Simone, this is a new direction for Children's Hospital, which years ago served as a convalescent care facility. The Hospital, located on land adjacent to Stanford Medical Center, is administratively independent. But it is affiliated with the Department of Pediatrics and is staffed by faculty physicians. Simone will hold an appointment as professor of pediatrics.

"This institution was originally built as a convalescent home, when the best treatment for chronic illnesses such as rheumatic heart disease was thought to be long-term hospitalization," says the physician.

"This has changed, because chronic diseases and treatment concepts have changed," he says. "We now minimize hospitalization time with more effective outpatient facilities so children can be at home most of the time. Also, we are dealing with diseases such as leukemia for which there are no uniformly effective treatments. It is our obligation to improve treatment through scientific study and research."

Simone denies that patient care suffers in a health facility involved in research. In fact, "there is a clear indication that the results of cancer treatment are superior in centers where research is being done," he says.

There are two basic types of research, says Simone. In a clinical investigation the physician designs a research protocol to apply treatments in an organized and systematic way, without necessarily involving any laboratory research. The second type, fundamental research in the laboratory, studies the disease process itself with potential benefit to patients in the more distant future.

"We have a young staff capable of doing the first type of research," says Simone. "We need people to do fundamental work and we will look for them over the next year or two."

Meanwhile, Children's Hospital will maintain the excellent patient care it now provides, he says. The parent-sharing program, where parents can live in with their children during hospitalization, will continue. And Simone hopes to increase the involvement of community physicians in the care of patients they have referred to the Hospital.

STANFORD –

Acupuncture offers nothing unique in relieving pain over other treatments such as hypnosis or biofeedback, according to Bernard Millman, assistant professor of anesthesia and director of the Department of Anesthesia's Nerve Block Clinic.

Millman who has headed the Clinic for four of the five years it has operated, has taken courses in acupuncture, but does not employ the technique in treating patients.

"It's not the acupuncture but the patient that reduces the pain," he says. "Most patients can control their own pain. They just need a tool to help them."

Helping patients find tools to reduce their pain, or at least find ways of coping with it, is the job of the Nerve Block Clinic. Millman and his associates evaluate the psychological as well as physiological backgrounds of the 10 to 20 patients they see each week to determine the best treatment for their pain.

Unlike other pain management clinics throughout the country which bring a variety of treatments to bear on chronic pain conditions, the Nerve Block Clinic employs only one diagnostic technique, the blockage of nerve conduction by local anesthetics such as lidocaine. This method can determine the pathway of pain transmission.

The Clinic members then recommend treatment which may involve taking or eliminating drugs and surgery or injections to destroy the involved nerves. Most chronic pain cannot be treated with nerve blocks alone. Many patients are therefore referred to specialists in the Medical Center and the community. Millman calls the Clinic "primarily a diagnostic resource for the community physician," similar to the hospital X-ray service.

The Clinic receives patients only on referral from their physicians, and when accompanied by complete medical records. And they also must take a psychological examination to determine what emotional factors, if any, are contributing to the pain.

Psychological testing also helps Millman and his associates to see what coping resources a patient has. "After six months of chronic pain, severe personality changes can take place in a patient," says Millman. Most patients come to the Clinic depressed and anxious, he says, and very concerned about illness. The presence of pain often affects their whole life styles, including interpersonal relationships.

"Many of these patients are seeking reassurance," says Millman. "They need help passing through the crisis period caused by the pain." Often, consultation can handle most of the emotional problems, and elaborate treatments may not be necessary.

Millman cites studies in which pain was reduced in 30% of the cases where placebos, drugs or procedures which have no physiological effect, were administered. Lessening of pain often results not so much from the type of medicine used as from the way it is administered. For instance, Millman said most patients respond better when drugs are injected than when they are taken orally. Even surgery may provide pain relief on a placebo basis.

Surgical destruction of nerves to treat pain is becoming less and less necessary, says Millman. "It is becoming more apparent that by controlling aggravating factors in the environment, the level of pain can be reduced," he says.

STANFORD –

A new element was added to Stanford's internationally famous Executive Program this summer—executive health!

Along with their studies of computers, economic management, international finance, and marketing, the participants learned about health management techniques, volunteered for a medical examination and regular supervised exercise, and received diet counseling.

The new feature of the Stanford Executive Program was cosponsored by the Stanford University Medical School and the Graduate School of Business.

The well-known Business School program has been held during the summers since 1952. This year 185 senior level executives, ages 35 to 50, were enrolled, including 62 from 24 foreign countries. The program, conducted by the faculty of the Graduate School of Business, ended August 11.

The health enhancement program was conducted by Drs. Robert DeBusk and William Haskell of the Stanford Medical School's Division of Cardiology and by other faculty of the School of Medicine.

Topics ranged from physical fitness, diet, and stress management to discussions of family and personal goal-setting. Because many health issues relate to the whole family, some of the lectures were scheduled during the final week of the program when spouses were invited to attend.

Most participants volunteered for a medical examination which included an evaluation of health-related habits and behavior, blood cholesterol, and triglyceride levels.

As in past years, participants were urged to use the University facilities for exercise and recreation. For the first time, this summer's group could volunteer for a special early-morning exercise program, conducted by Stanford Heart Disease Prevention Program personnel.

This special group of about 30 executives was screened to determine how much physical exercises would be appropriate for each. Then Dr. Haskell and his staff supervised warm-up exercises and a one- to four-mile jog through campus every morning.

"Good physical health is critical to executive effectiveness," says Professor James Howell, director of the Stanford Executive Program. "As a group, executives lead a life that is prone to stress and related health problems."

Program directors reasoned that the two-month change in routine would provide an ideal opportunity for executives to develop new health habits.

Says Haskell, "The participants are old enough to realize they are not invincible. They are successful and headed toward even more productive careers. . .we wanted to give them some useful tools for maintaining good health."

Those who participated in the daily supervised exercise will be asked in several months to evaluate the effectiveness of the program and its impact on health habits after they return home.

"I have the best of intentions to continue this at home," says Peter Frey, general manager of an insurance company in Munich. "It has been a great change for me, since I had never exercised, except for sailing once a year."

Phil Oxley, an oil executive from Houston, cited the value of "the peer group that would frown at you if you didn't show up" for the 6 a.m jogging.

David Eller, a beef industry executive from Houston, reports that the program gave him the confidence to pursue a strong exercise program based on physical examination and medical supervision. "We found our 'floorboard' capabilities, the maximum exertion your body should take. . .and we learned to take our pulse rate during exercise and understand what it means."

Eller cited a "tremendous change" because of the regular exercise. "I've taken off some weight and am in better condition."

FOR IMMEDIATE RELEASE
STANFORD –

Stanford University School of Medicine officials have told the federal government they would rather forfeit $410,000 in federal educational support than agree to accept students who do not meet Stanford's standards for admission.

Stanford's intentions were spelled out by Dean Clayton Rich of the School of Medicine in a letter accompanying the school's application for funds under the Health Professions Educational Assistance Act of 1976.

The Act requires medical schools to waive their own academic standards in order to admit American medical students enrolled abroad who would pass the basic science portion of the national board examinations. No other academic qualifications could be considered. The law is in effect for three years, and any school refusing to accept this provision would lose its educational subsidies.

In his letter, Rich said the University must take exception to the requirements imposed by the law with respect to the admission of students who do not meet the School's own standards for admission.

"We believe it is essential for the academic integrity and independence of universities that the critical judgments about standards for admission and the quality of applicants be made by the University and not given over to an agency of the government," Rich said.

In a separate statement, Stanford University President Richard W. Lyman said Dean Rich has acted to protect the interests of the entire University.

He said in requiring that medical schools waive their normal admission standards to qualify for educational subsidies, the Congress inadvertedly had established a precedent.

"The University cannot accept this without giving up its own self-determination of basic academic decisions," Lyman said. "If, as a result, we must do without $410,000 a year, that will be painful, but in the long run far less so than the consequences of accepting this unfortunate provision.

"Our job now is to help those in the Congress who want to change the law. I hope that can happen without delay."

Rich said that Representative Paul G. Rogers (D-Fla.), chairman of the House subcommittee that handles health manpower legislation, had introduced a bill to modify the law.

Rogers' proposal would require that schools expand third-year enrollment by 5% or 10 students, whichever is greater, but would remove the requirement that each school set aside its own criteria for selection of students.

His aim, he said, in a letter to colleagues, is to make the provisions more feasible to administer, and remove the features to which medical schools object.

"Those efforts will have my enthusiastic support," said Rich. "Stanford's participation in the important programs of the Act would be to everyone's benefit.

"I hope in the near future it will be possible to provide assurances that do not compromise the University's central academic values."

Stanford officials said they are waiting to see the outcome of the Rogers' proposal as it moves through Congress. If it fails and the Act remains intact, they believe it could be challenged on legal grounds.

Last year when the Act was passed Dr. Rich and several other deans had protested the potential loss of their schools' control over admissions. And the council of deans of the Association of American Medical Colleges at a meeting in San Francisco voted unanimously to protest the government's "intrusion into academic processes."

FOR IMMEDIATE RELEASE

Science Writers: Following is a sidebar concerning the role of Stanford University researchers in a national study of treatment of serious viral diseases.

STANFORD –

Medical practice may be entering a new era of antiviral therapy, a Stanford University researcher said Thursday, Aug 11.

Dr. Thomas C. Merigan, professor of medicine and head of the Division of Infectious Diseases, was commenting on a government announcement showing the first successful drug treatment of patients with herpes encephalitis.

The drug used–adenine arabinoside, or ara-A–significantly reduced both neurological damage and deaths due to this highly fatal brain infection, according to a press release issued by the National Institute of Allergy and Infectious Diseases in Bethesda.

In the carefully controlled, double-blind study comparing ara-A and a placebo, ara-A treatment reduced mortality from 70 to 28 percent, according to the story. In addition it significantly decreased the degree of debilitating after-effects in those who survived.

Merigan's group was one of 15 university investigative teams that participated in the study. "We are quite pleased at the beneficial results of the drug," he said.

He added that ara-A appears to have beneficial effects in the treatment of other virus infections being treated at Stanford

"We are developing agents to treat viral disease which will have the same potential of the early efforts to control bacterial infections with antibiotics," Merigan said.

At Stanford, the researcher said, ara-A is being studied concurrently with another substance called human interferon. These are first generation effective antiviral agents that Merigan hopes will be added to medicine's weapons against viral disease.

Last year Merigan and his colleagues reported the most significant clinical result thus far with interferon in treatment of chronic hepatitis B infection.

In the U.S. about 10 percent of patients hospitalized with acute hepatitis B become chronically infected–that is, they continue to carry the virus in their blood, and are potential transmitters of the infection.

No effective treatment has been available and spontaneous recovery from hepatits B infection is rare.

STANFORD –

The reputation of Stanford University School of Medicine is listed among the top in a comparison of 87 medical schools in the nation, according to a recent report.

The study examined the reputations of American medical schools for quality of faculty and effectiveness of training, as assessed by a survey of physicians and scientists of the schools

Jonathan R. Cole and James A. Lipton of Columbia University reported the work in a recent issue of the journal *Social Forces*.

Harvard ranked first in the survey, followed by Johns Hopkins and Stanford, both rated at the same level.

Characteristics of the medical schools that were instrumental in determining the ratings, according to the researchers, include the eminence and size of the faculty, training and research grants available, research and publications, and perceived effectiveness of training.

To obtain the ratings, questionnaires were sent to 2,049 full-time faculty in clinical and basic science departments. They were asked to rate medical schools for the quality of their faculty and training programs, and what factors they considered important in making the evaluations

The investigators reported that medical school reputations depended largely on their performance as scientific and research organizations. "Schools with the greatest resources in support of research, with faculty producing the most research, and with faculty recognized and honored for their research performance, were rated most highly,"they report.

STANFORD--Eight Bay area community leaders and six Stanford faculty members and administrators have been named to the Stanford University Medical Center Council.

Their appointments were announced by Stanford University trustee William E. Ayer, council chairman.

Formed recently, the council sponsors and coordinates efforts to develop private gift support for the Medical Center.

According to Dudley Kenworthy, director of development, this is the first centerwide high-level fund raising group in existence at the Medical Center since the mid-1950's. At that time, a similar committee, led by the late Herbert Hoover and San Francisco community leader Parmer Fuller directed the fund drive for the construction of the Stanford Medical Center complex.

Ayer said the medical center provides highly specialized and technologically sophisticated medical care for a wide California area. For the treatment of some diseases, patients come to Stanford from all over the United States and from abroad.

He said fund raising is receiving top priority at the center because the hospital is overcrowded. Some new space is needed along with remodeling of present space in which to develop the particular programs of patient care, teaching, and research conducted at Stanford.

In addition to helping with funding for new facilities, the council will seek program support. Patient fees contribute minimally to construction and the teaching and research functions. Unlike most California hospitals, Stanford has no local or state tax income for these purposes.

The leaders named to the council have been active in other efforts associated with the medical center. They are: Dr. Victor Richards, San Francisco, Medical Alumni Association; Dr. David Rytand, Atherton, Stanford Medical Alumni Fund and Medical Alumni Association; Mr. and Mrs. James G. Shennan, Jr., Atherton, Stanford Program for Pediatrics; Jack L. Shepard, Atherton, Medical Center Friends; Mrs. Marie Strain, Menlo Park, Medical Center Auxiliary; Melvin C. Ury, San Francisco, Friends of Radiology; and Mrs. O. Meredith Wilson, Palo Alto, Board of Hospital Directors.

-more-

Faculty are represented by Dr. Jack D. Barchas, Nancy Friend Pritzker Professor of Psychiatry; and Dr. Thomas C. Merigan, professor of medicine and head, Division of Infectious Diseases.

Medical center administrative staff on the council includes Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine; Peter Levin, associate vice president for medical affairs; Paul B. Hofmann, director of the hospital and clinics; and Dudley C. Kenworthy.

Several additional members will be appointed to the council in the near future, Ayer said.

During the coming year the council will sponsor a number of public events including the Progress in Medicine Lectures.

ADVANCE FOR P.M. RELEASE MONDAY, OCTOBER 3, 1977

STANFORD –

A television test for visual screening of the viewing public has been devised by ophthalmologists at the Stanford University School of Medicine.

The screening consists of a brief videotaped sequence combining two eye tests—one for visual acuity, the other for visual field. The test is devised to be effective regardless of the size of the viewer's television screen.

Each eye will be tested separately. The visual acuity part of the test is dependent upon the viewer's ability to see letters of varying sizes on a television screen. For visual field testing the viewer is instructed to look at a dot in the middle of the picture while spots located strategically around the screen rapidly blink off and on.

The test, along with the necessary introductions and explanations, runs 20 minutes and the viewer grades his own results. If he passes, fine. If he fails, he will be urged to see an ophthalmologist.

Examples of diseases which could be detected by these screening tests are glaucoma, retinal degeneration, cataracts, and disorders of the central nervous system, such as brain tumors.

The television eye test was developed by Drs. Milton Flocks, a clinical professor of ophthalmology, A. Ralph Rosenthal, head of the division of ophthalmology, and Jerry Hopkins, working under a grant from the National Society for the Prevention of Blindness.

The Stanford researchers described the test Monday, Oct. 3, at the meeting of the Academy of Ophthalmology and Otolaryngology in Dallas, Texas.

Dr. Flocks said the two most valuable and effective visual screening procedures in the past have been the testing of vision in school children and the testing of automobile drivers by state licensing bureaus. These agencies normally disover and refer for eye examinations large numbers of persons.

"It occurred to us," said Flocks, "that the medium of television with its unparalleled potential for reaching the public might be used as a convenient and inexpensive means for visual screening."

There are large numbers of people who have visual field defects and decreased visual acuity in one or both eyes who are unaware of their abnormality, he said. Serious efforts should be made to identify and treat these individuals.

Flocks said the videotaped sequence was tested at the Stanford Eye Clinic under controlled conditions in 156 individuals, all of whom had undergone an eye examination. Of those tested 88 had known visual abnormalities while the remainder were normal.

"The comparison of results of the screening tests with clinical opthalmologic examination indicated that TV testing could detect about 90% of those individuals with a significant visual abnormality. Conversely, in the clinic 10% of the normal individuals failed the test.

The authors state the eye test could be compared to the breast self-examination performed by women on a widespread basis which is undoubtedly of great value in spite of some false positive and false negative results.

Flocks and Rosenthal suggested that the vision test could be first made available to small communities so that its effect on the public can be studied before more widespread broadcasting.

At some later date with proper publicity and network broadcasting of the vision test, an enormous audience could unquestionably be reached.

FOR IMMEDIATE RELEASE

STANFORD –

The Stanford University School of Medicine has been granted $500,000 for five years from the Bristol-Myers Company to support basic and clinical cancer research, the Company announced Wednesday, Sept. 28, in New York.

Dr. Saul A. Rosenberg, professor of medicine and head of the Division of Oncology, said Stanford will use the grant primarily to expand programs in clinical pharmacology, and in the development of "combined modality therapy." This involves the use of one or more anticancer drugs in combination with other types of treatment such as surgery, radiation, and the still-experimental field of immunotherapy.

There is increasing evidence, said Rosenberg, that combined modality therapy "may be one of the most effective approaches to the treatment of some forms of the disease, including childhood cancers, leukemia, and lung cancer."

Initially, Stanford's research will be on malignant lymphomas, of which the best known is Hodgkin's disease. Pioneering therapy for Hodgkin's disease developed at Stanford has already resulted in highly effective treatment of up to 90% of patients when treatment is initiated at an early stage.

Stanford's grant is one of a $2.5 million program for the next five years initiated by Bristol-Myers. Other schools receiving grants are Yale, Johns Hopkins, Chicago, and Baylor, the company said.

"Our objective is to provide these schools with funds on a no-strings basis to encourage excellence and innovation in cancer research, and to permit them to explore promising leads in depth," said Richard L. Gelb, chairman of Bristol-Myers.

In addition, Bristol-Myers announced the establishment of an annual $25,000 Bristol-Myers prize to a research scientist who has made an outstanding contribution to progress in cancer research. Recipients will be selected by a committee made up of the heads of the cancer programs in each of the medical schools receiving grant funds.

Medical schools and cancer research centers throughout the country will be invited to nominate candidates for the first year's prize in the spring of 1978, the Company said.

FOR IMMEDIATE RELEASE
STANFORD –

Duane D. Walker, R.N., M.S., has been named associate director of Stanford Hospital and director of Nursing Service.

Walker, 39, has served as assistant administrator and director of nursing at the University of Utah Medical Center since 1975. He will begin new duties at Stanford on January 9, 1978.

Walker succeeds Margaret Neill, who resigned in December 1976. In the interim Lois Williams and Richard Pettingill have been acting codirectors of Nursing Service.

In announcing the appointment, Paul Hofmann, director of Stanford Hospital and Clinics, commented that "we are delighted to be able to fill such a vital position with someone with qualifications and experience as impressive as Walker's."

Walker received his undergraduate degree from Weber State College, Utah, in 1964. He served as administrator with Pioneer Memorial Hospital in Brigham City, Utah, before entering the U.S. Army Nurse Corps as an in-service education instructor.

He served as assistant administrator and director of nursing services at Holy Cross Hospital in Salt Lake City from 1970 to 1975. He is currently an instructor of nursing in the University of Utah College of Nursing, as well as assistant administrator for patient care services at the University of Utah Medical Center.

Walker is active in several nurses' associations and community organizations. He has a strong interest in research activities, and has authored several papers in the nursing field. His master of science degree in 1975 from the University of Utah is in psychiatric nursing.

FOR IMMEDIATE RELEASE

STANFORD –

Two Stanford researchers expressed shock and surprise Monday, Sept. 27, on learning that their work during the late 1950s had been covertly sponsored by the Central Intelligence Agency.

Dr. Marion Smith, now an adjunct professor of neurology, and Dr. William Hofmann, associate professor of neurology, both said they were certain that their colleague, Dr. Wallace Lane Chan, had served as the CIA's liaison at Stanford.

Contacted at the Norwood-Foxboro Health Clinic in Massachusetts, Chan flatly denied having worked for the CIA while at Stanford, either directly or indirectly. He said he had been employed by the agency overseas from 1953 to 1957.

At a campus news conference, Smith said it was common knowledge that her studies of alcohol absorption, conducted with the late Dr Henry Newman, had been funded by the Geschickter Fund for Medical Research, Inc. This has been publicly identified by its founder in U.S. Senate hearings as a CIA conduit.

Hofmann, who succeeded Newman as acting head of the neurology division in 1959, said he was "quite shocked" to learn about the CIA involvement and had "worried about Chan" years ago. Currently on leave in Munich, Germany, Hofmann first learned of the CIA's role during a phone call from Dr. David Prince, chairman of neurology, Monday afternoon.

Chan said he didn't remember Smith, but had worked with Newman on alcohol studies and with the late Dr. Windsor Cutting on pharmacological studies involving fish in 1958.

He replied affirmatively when asked if he and Cutting were studying "the neurophysiological and pharmacological effects of central nervous system antagonists and synergists."

These words are identical to those used in an internal CIA document to describe a project conducted at Stanford as part of the CIA's Project MK-ULTRA during 1957-58.

In a file memo, Sidney Gottlieb, CIA's director of technical services, noted that while the work would be done in the Stanford Department of Pharmacology, a faculty member from the Department of Medicine "will be able to monitor, direct, and actively participate in this project" from the standpoint of agency interests. (Payments totaling $41,382 subsequently were made to the University through a covert CIA foundation conduit it for the pharmacology project.)

On the same day—May 1, 1957—Gottlieb wrote another file memo concerning a separate MK-ULTRA project which subsequently led to the direct payments of $28,800 to an unidentified assistant clinical professor of medicine at Stanford between September, 1957, and June, 1961, mostly in the form of cashier's checks for $800 per month.

This period corresponds with Chan's employment at Stanford in that field at that rank. He vigorously denied having either requested or received such funds. "I never got $800 checks. I had to earn every penny," Chan declared.

(more)

Gottlieb's memo on the direct payments said this project's purpose was to enable the agency "to continue the utilization of (name deleted), presently at the Department of Medicine, Neurology Division, Stanford."

The unnamed individual's responsibilities included monitoring the Newman studies on alcohol and the pharmacology project. Chan confirmed his involvement in both projects to Stanford News Service and told *The San Francisco Chronicle* he knew Gottlieb.

Gottlieb's memo on the direct payments project said this person also would "plan, monitor, and direct research and development of a miniaturized polygraph," and conduct "clinical testing and evaluation of various antiinterrogation preparations."

Chan flatly denied having done any such work.

Further file memos on the same project in 1959 and 1960 expanded its scope to include "review of overt Chinese and Japanese pharmacological and physiological literature," In a standard "memorandum of agreement," signed July 1, 1957, the recipient pledged "never to divulge, publish, nor reveal" information about the project.

At the news conference, Smith said the source of funds for the alcohol studies was "never very clear," although Newman had indicated it was government sponsored when he employed her on the project.

Smith said she was told there were "practically unlimited funds available to work on anything concerning the rate of alcohol metabolism." Over the ensuing five years "everything I did was published" in about 10 professional journal articles.

No human volunteers were involved in her studies, which were limited to dogs, rats, and mice. Chan saw copies of her work and "I knew he was the liaison for funding," but there was no attempt to influence her findings or their publication, Smith said.

"I was happy to have a job, to do what I wanted, and get published a lot." Prince described the quality of her scientific work as "outstanding," a view shared by other scholars at Stanford.

Smith recalled that Newman had done some studies on the effect of alcohol on sleep involving human volunteers. He found that alcohol probably made people sleep less well. Whether this was part of MK-ULTRA was not completely clear.

Newman, who died in 1959, "was very friendly, a nice man, very honest," Smith said. He was nationally known for his alcohol studies.

FOR IMMEDIATE RELEASE

STANFORD –

Between 1953 and 1961 the Central Intelligence Agency covertly spent nearly $390,000 on Stanford faculty research as part of its nationwide project MK-ULTRA "to identify materials and methods useful in altering human behavior."

Of this total, more than $347,000 was paid through a foundation conduit for five University projects. Cashier's checks were used to pay faculty more than $40,000 directly for two smaller-scale efforts.

The first of these, running from May 1953 through January 1957, provided $11,478 for "services as a contact and cut-out for projects in the MK-ULTRA field" to a "practicing psychiatrist" on the Stanford medical faculty, which then was based in San Francisco.

(Personal diairies of the late George Hunter White, a former federal narcotics agent and CIA liaison, mention his drug experiments with Dr. James Hamilton, a psychiatrist now retired from the Stanford clinical faculty in San Francisco. Dr. Hamilton has declined to respond to numerous press inquiries.)

The seven projects at Stanford were among 135 or more nationally. They included research on alcoholic intoxication, analysis of sedatives for Project Knockout, development work on a miniaturized lie detector, and a literature search on blood groupings, among others.

All involved Medical School faculty, mostly in the Division of Neurology. These activities declined sharply following the death of Prof. Henry Newman, the division chairman, in 1959 and the School's move from San Francisco to Palo Alto the same year.

These broad, tentative conclusions emerge from a preliminary overview of more than 500 pages of CIA documents provided the University at the request of President Richard W. Lyman. Received Friday, Sept. 23, they have been duplicated and made public.

Stanford has barred secret research since 1969.

The CIA documents have most names deleted. They provide little evidence of what research was actually conducted. The great bulk of the documents is financial.

The largest single project was a study of alcohol and tranquilizers originated by Newman. CIA authorized $147,255 for this during 1956-60, apparently using a foundation conduit.

This study was aimed, in part, "at permitting consumption of larger amounts of ethyl alcohol without an increase in nervous system depression." While Newman is not named, he was the only person to have the titles used in correspondence concerning the project. Well known for his research on alcohol, he was a Stanford graduate (A.B., 1927, M.D., 1931) and faculty member from 1932 until his death.

The second largest project was funded through a foundation for $114,373 from 1957 to 1961. Its objective was "fundamental information" necessary for "a highly potent, quick-acting substance that will render an individual helpless and immobile, preferably in an unconscious state."

Part of Project Knockout, it included study of the sedative effects of certain species of ticks. "As a byproduct of Project Naomi, a sizable amount of this neurotropic substance is being isolated," one report noted.

While the "cut-out and cover" organization was editorially obliterated, one internal memo boasted that "(blank) will monitor and direct and actively participate as principal investigator. . .arrangements have been made for his appointment."

During 1957-58 MK-ULTRA used a foundation conduit for $42,065 in research "on the neurophysiological and pharmacological effects on central nervous system antagonists and synergists."

(more)

An internal memo indicates this may have been lodged in the Department of Pharmacology in San Francisco but an individual in the Department of Medicine, which then included neurology, "will be able to monitor, direct, and actively participate. . . ."

From 1957 to 1961, direct payments totaling approximately $28,800 were made "to continue the utilization of (a physician), presently located at the. . .Neurology Division. . .on project activities."

Its objectives included participation in clinical testing and evaluation of drugs useful in resisting interrogation, review of overt Chinese and Japanese pharmacological and physiological literature, and "report on general scientific and medical meetings attended," among others.

On this and several other projects, investigators had "top secret" clearance and signed a standard "memorandum of agreement" with CIA. This states, in part:

"I solemnly pledge my word that I will never divulge, publish, or reveal either by word, conduct, or by any other means such information or knowledge (gained from research). . .unless specifically authorized to do so."

The CIA interest in portable polygraphs and blood typing is explained in an internal memo which states: "Today, because of rapid changes and reassignments of our overseas case officers and the continuing operation of agents (words deleted) for long periods of time, the paramount question arises upon the exfiltration of the agent(s): Is the agent 'bona fide;' is he the same person we started with?"

Besides lie detectors, blood groups, and biographic files, the CIA author suggests that radioisotopes or radiologically opaque foreign bodies might be selectively implanted in agents to help solve this problem.

The same memo notes that "The very way clandestine services operate. . .involves highly complicated 'tradecraft' techniques, clandestine agent recruitment and handling, nets and subnets, security and reliability of communications, and so on.

"Isolated by the security barrier, the perfecting of these techniques sometimes threatens to become an end in itself."

The CIA documents show the agency spent $41,382 for development of three miniaturized lie detectors at Stanford, using the foundation as conduit. Results of this 1958-59 project in the Division of Neurology were assessed as "satisfactory."

The smallest project was for a literature survey and information on minor blood groupings. Channeled through a foundation, it resulted in payment of $1,040 to "a leading investigator on blood groups in man" in 1958.

In describing the qualifications of the initial, direct-payment operative in 1953, an internal memo said he had served as chief neuropsychiatrist at one institution, chief of the psychiatric section at another, and had World War II experience with the Office of Strategic Services (OSS), a CIA predecessor.

"He has been of value in the general MK-ULTRA field as an overall adviser and consultant, he has been of value in contacting individuals. . .and he has done work himself which has contributed to the MK-ULTRA field," the memo noted.

The CIA records show this individual was directly reimbursed for payments to five informants during 1956 totaling $1,680. These were approved by Sidney Gottlieb, chief of CIA technical services and one of the most prominent agency officials to be identified in the current Senate probe of MK-ULTRA.

The New York Times, which broke the first major story on this research, said some 86 institutions were involved in the national program, which cost an estimated $25 million over 25 years.

Copies of the documents sent Stanford by the CIA have been distributed to several University officers, major newspapers with a continuing interest in the disclosures, the Stanford Library, and Stanford Archives.

FOR IMMEDIATE RELEASE

STANFORD –

A man masquerading as a Stanford physician was discovered by paramedics after a ride in an ambulance Thursday morning. He was arrested later by officers of the San Mateo Sheriff's Department.

Lieutenant Brendan Maguire of the Departmentsaid the man, identified as Edward Ingram, was cited for impersonating a physician and possession of a physician's name tag.

Ingram contacted two paramedics of the Medivac ambulance service of San Mateo in Stanford's emergency department Thursday morning, according to John Scott, chief paramedic at Medivac.

He was wearing a white lab coat with the name tag of Dr. Morris O. Daily, a pathology intern, said Scott. He identified himself as Dr. Daily, and asked if he could ride along.

Scott said physicians commonly ride along with paramedics without assisting in medical care to get an idea of what is involved in field emergency treatment.

Ingram only observed, except to take some blood pressures, said Scott.

Ingram also had ridden with Medivac paramedics late Monday night, he said.

The paramedics notified the Sheriff's Department after discovering he was not Daily. Ingram was picked up by officers at 2 p.m. Thursday in a Menlo Park restaurant, Maguire said.

FOR IMMEDIATE RELEASE

STANFORD –

Dr. Hugh O. McDevitt, professor of medicine and member of the division of immunology at the Stanford School of Medicine, has been named winner of the annual Borden Award for outstanding research from the Association of American Medical Colleges (AAMC).

The award consists of $1,000 and an inscribed gold medal. It will be presented to McDevitt Nov. 8 at the annual AAMC meeting in Washington, D.C. Dr. John A.D. Cooper, AAMC president, announced McDevitt's selection Wednesday, Sept. 21.

McDevitt, 47, was cited for his pioneering work on the genetic controls of the immune response.

His group discovered that the genes controlling the ability of the body to respond to foreign materials are clustered together on one chromosome in the mouse, and are closely linked to the genes responsible for the transplant rejection reaction.

Rejection of transplants is elicited by markers produced by these genes, called transplantation antigens, which are located on the surfaces of cells.

"In the past five years investigators throughout the world have found that over 30 human diseases are associated with particular transplantation antigen types," says McDevitt.

"It is apparent that this complex set of (immune response) genes clustered in one small region on the sixth human chromosome is a major regulator of immune responsiveness," he says.

A native of Cincinnati, Ohio, McDevitt obtained an AB with honors from Stanford (1952) and his M.D. from Harvard Medical School (1955). He taught bacteriology and immunology at Harvard before coming to Stanford in 1966.

McDevitt became interested in the inheritance of immune responses in 1963 while doing research at the National Institute for Medical Research in Mill Hill, England.

He continued his work at Stanford, where he found that the immune responses of mice were closely correlated with the transplantation genes.

This discovery led to the identification of some 30 immune response genes.

McDevitt's group is now studying how the normal immunological mechanisms of the body protect against cancer, and how modification of these mechanisms might possibly treat or cure the disease.

Recently McDevitt, his coworkers, and Dr. Peter Stastny of Dallas have found genetic markers in the white blood cells of patients with rheumatoid arthritis.

The Borden Award, presented annually since 1947 by the AAMC in cooperation with the Borden Company Foundation, is given in recognition of "outstanding research in medicine conducted by a member of the faculty of an affiliated college."

Other Stanford faculty members who have received the award are Dr. Arthur Kornberg, Merner professor of biochemistry (1968), for his work on synthesizing DNA, and Dr. Thomas C. Merigan, professor of infectious diseases (1973), for developing techniques to treat virus infection with interferon.

Last year's winner was Dr. Roger C.L. Guillemin, resident fellow and research professor at the Salk Institute in La Jolla, California, and adjunct professor of medicine at UC-San Diego.

He was cited for research in neuroendocrinology, in which he and a colleague isolated and synthesized three hormones produced by the hypothalamus in the brain

Birth marks, beauty spots, strawberry patches, port wine stains!

These colorful names for pigmented skin lesions, and objects of concern for mothers of newborn infants, were discussed at a Pediatric Dermatology Symposium at Stanford Medical School Friday, September 16.

''A small number of such skin lesions may develop into malignant melanoma,'' said Dr. Robert Walton, a clinical professor of dermatology. Malignant melanoma is a particularly virulent form of cancer that can spread rapidly through the body.

But if it is diagnosed at an early stage, he said, it is a curable disease.

Moles should be removed, said Walton, when they show any ''progressive change, including increase in size or shape, change in color, the way they feel, or whether they scale, crust, or bleed.''

But it's difficult to tell the difference between normal changes in moles which accompany the growth of the child and pathological change, he said.

Some lesions have a greater risk of becoming malignant and should be biopsied, said Walton. These include lesions which cover large portions of the body, so-called garment lesions. About 10 percent of these become malignant, he said.

However, physicians do not know what constitutes a ''large'' lesion and therefore a higher risk of cancer, Walton said. ''If it is sufficiently large to be noticeable, it should be biopsied,'' he said.

Walton said lesions in certain locations have higher risks of malignancy and should be biopsied as a matter of course:

-In mucous membranes in the female genital region, moles are 70 times more prone to develop malignancy than in other areas.

-Under the finger or toe nail, although rare, moles give rise to about 3 percent of all malignant melanomas.

-On the palms and soles, moles have a 20 percent greater chance of becoming malignant that other parts of the body.

Physicians do not know why some moles become malignant, while others remain benign all through life. They do know that irritating or scratching moles will not cause them to develop cancer.

Walton and Dr. Alvin Jacobs, professor of dermatology, did the first study of the effect of controlled trauma on moles. They found deliberate cauterization caused no significant change in moles even 20 years afterward.

They also pioneered in research on the percentage of babies born with pigmented lesions. They examined over 1,000 babies, and found that 4 percent of them had pigmented lesions present at birth.

None of these appeared to be potentially malignant, Walton said, although two lesions showed changes which could be interpreted as similar to those of the garment-type lesion.

Follow-up studies for a period of years are needed on these children, said Walton, to determine what percentage, if any, of the moles present at birth become malignant.

STANFORD –

A major program will be instituted at Stanford University Medical Center to help counter the claim that "in arthritis, nothing can be done."

The Stanford Arthritis Center, with a three year $335,000 grant from the National Institutes of Health, will conduct studies to determine what methods of therapy are most effective and which health personnel can best provide that care.

Stanford is one of 15 institutions in the nationwide program established under the National Arthritis Act of 1975.

According to Dr. Halsted Holman, professor of medicine and director of the new Arthritis Center, the skepticism that little can be done about arthritis is not valid.

But, he says, a system is needed to evaluate the effectiveness of particular methods of treatment.

Specific aims of the Stanford Center include designing a system to evaluate patient outcomes, the usefulness of patient education programs and self-care, the effects of rheumatologic surgery such as total joint replacement, and the benefits of new medications.

Even without introducing new therapies, says Holman, there can be meaningful improvement in patient outcomes.

He cites such improvements as shorter hospital stays for some diagnoses, prehospital testing, noninvasive measurement techniques, recall of some drugs and decrease in use of others, and mandatory consultation in some circumstances.

Needing attention, he says, are items like redundant and expensive procedures without benefit, side effects from nonindicated medications, unnecessary surgery, and unneeded office visits, laboratory, or X-ray procedures.

For example, he says, some physicians feel that bed rest in rheumatoid arthritis, in a hospital, will decrease inflammation and symptoms, and allow the disease to be managed with fewer drugs. Others say such treatment increases the rate of bone loss and muscle atrophy, and the benefits will not last longer than the hospitalization.

"Obviously, such controversy is of major importance; the answer must lie in evaluation of the effects of the treatment over the long term. Such outcome has not been adequately studied," says Holman.

Holman notes that Stanford has long been involved in such questions. During the past six years in the Stanford Arthritis Clinic, cost per patient and per patient visit has decreased by more than 25 percent, principally because of more selective laboratory procedures.

During the same period the number of patients has doubled, the number of hospitalizations halved, and mortality in systemic lupus erythematosus and other connective tissue diseases has decreased, without change in treatments.

Another aspect of the Stanford program will be evaluation of what kinds of health personnel can provide the most effective care.

Roles of the nurse-practitioner, the physical therapist, social worker, patient advocate, and others will be examined. A further study will compare patient outcomes achieved by such a multidisciplinary group and by treatment from a physician alone.

Another part of the program will involve examining the outcome of 300 adults who were afflicted with arthritis as children.

The Stanford program will utilize the American Rheumatism Association Medical Information System (ARAMIS). Dr. James Fries, assistant professor of medicine and associate director of the Stanford Arthritis Center, is director of the ARAMIS nationwide data bank.

Its aim is to make available to physicians information about a cross section of patients, their treatments and outcomes. Such information, says Fries, provides for more accurate prognoses and therefore more effective therapeutic programs.

Portions of the new program will be conducted at Stanford and at affiliated hospitals, including the Palo Alto Veterans Administration Hospital, Santa Clara Valley Medical Center, and Children's Hospital at Stanford. Physicians in private practice and groups such as the Mid Peninsula Health Service will also be involved.

FOR IMMEDIATE RELEASE

STANFORD –

Dr. Ralph S. Paffenbarger, Jr., a leading figure in the field of epidemiology, has been appointed professor of family, community and preventive medicine at Stanford University School of Medicine.

He will head a new division of epidemiology at Stanford.

Paffenbarger's appointment was announced by Dr. Clayton Rich, vice-president for medical affairs and dean of Stanford Medical School.

Paffenbarger has studied a wide range of infectious and noninfectious diseases, including cancer, heart, and mental diseases.

He plans to continue his present research on the relation of vigorous exercise to the development of heart disease in San Francisco longshoremen. He will also continue investigating the pathogenesis of disease in former college students, and the causes of certain types of cancer.

Paffenbarger, 54, left a post as adjunct professor of epidemiology in the University of California School of Public Health he held since 1969.

Previously he taught biostatistics and epidemiology at Harvard. He served as medical director in the U.S. Public Health Service for 21 years until his retirement in 1968.

Paffenbarger is past chairperson of the epidemiology section of the American Public Health Association. Currently he is the associate editor of the s,American Journal of Epidemiolog

A native of Columbus, Ohio, Paffenbarger did his undergraduate studies at Ohio State University. He received his medical degree from Northwestern University Medical School, and his doctorate in public health from Johns Hopkins University School of Hygiene and Public Health.

Paffenbarger is married and has six children, the youngest of whom is a freshman in college.

FOR IMMEDIATE RELEASE

STANFORD –

There's little you can catch from your family pet, says a Stanford researcher.

Dr. George H. Muller, well known pioneer in the field of small animal dermatology, says "children are quite safe with a pet. A visiting aunt can give them a cold more easily than the puppy who kisses them."

Muller spoke at a pediatric dermatology symposium at Stanford School of Medicine Wednesday, Sept. 14. He is clinical professor of dermatology at Stanford, and specializes in small animal dermatology in his veterinary practice.

The dog or cat who has been a household pet for years will almost never transmit a contagious disease to its owners, says Muller.

Most animal skin problems are not contagious, he says, and all are curable.

"Humans catch diseases from other humans, and puppies from other puppies," he says. Common scabies infections are contracted from fleas, ticks, and lice, usually from poor sanitary conditions while the animal is young.

Muller says it's okay for children to hug and carry their pets in their arms, if some preliminary rules are observed.

Pets, he says, should only be bought from a reputable dealer who has good sanitation practices.

Every new pet should be taken to a veterinarian for a check-up as well as immunizations, to spot any diseases.

Muller's final rule is that the owner should carefully look the animal over, too, since skin diseases are observable.

Fleas, ticks, and lice, he says, may infect an animal, but will only enter human skin by accident and then leave after a day or so.

Mites may invade human skin temporarily too, he says, but once the animal is treated, the human disease will disappear too.

"The cure of canine scabies in man is accomplished by eradicating the mites from the affected dog," says Muller.

The veterinarian described a recently identified mite, now seen in growing numbers, called Cheyletiella. It is commonly called "walking dandruff," since it is so large it can be seen fairly easily.

The Cheyletiella mite can produce skin disease in man by direct contact with infected pets. But constant animal contact is usually needed to maintain the human infection.

The mite is highly contagious, especially between puppies, and is often found in litters or pet shops where sanitation is poor. Adult dogs are usually lightly infected, even when in contact with infected puppies.

Muller says the animal infection is easy to treat.

Other skin diseases in animals, such as ringworm, hookworm, and fungal infections, he says, are rare, and can be treated.

FOR IMMEDIATE RELEASE

STANFORD –

Washing your face and avoiding chocolate will not keep you from getting acne.

Dr. Robert Roth, a Modesto dermatologist and clinical assistant professor of dermatology at Stanford, feels the avoidance of certain foods and the role of hygiene have been overstressed in treating acne.

Roth spoke at the Wednesday session of the Pediatric Dermatology Symposium in the Fairchild Auditorium of the Medical School. The symposium was presented by the Department of Dermatology.

Nearly every child develops at least one manifestation of acne, said Roth, from whiteheads and blackeads to severly inflamed cysts.

Most cases of acne will clear up in time. But, he said, it is important to treat acne, not only to prevent permanent physical scarring, but for the emotional well-being of the patient.

White heads are clumps of shed skin cells, fats, and a bacteria in hair follicles which are associated with sebaceous glands. Sebaceous glands produce the fatty acids which help give skin its oily appearance.

Blackheads are those clumps which are open to the air. Roth said the black color is not due to dirt, but may be the result of fatty acids oxidizing when exposed to air.

Pimples, cysts, and other inflammations associated with more advanced stages of acne are thought to occur when the hair follicle ruptures, spilling its contents into surrounding tissue, said Roth.

Some fatty acids can rupture hair follicles. Roth said the bacteria in the clumps may produce these fatty acids by breaking down larger fat molecules.

Acne can be controlled if the clumps of fats and bacteria are removed from the skin, or if the bacteria are killed with an antibiotic, Roth said.

Roth cautioned against pinching or squeezing white heads and black heads, because this can rupture the hair follicle and cause other acne eruptions.

Vitamin A, called "retin A," is the most effective agent presently available for removing the clumps from the skin, said Roth.

"Retin A is the only agent applied to the skin which does prevent blackhead and whitehead formation," he said.

(more)

Abrasive soaps generally are not effective he said, and can rupture the follicles.

The most effective antibiotic in treating acne is tetracycline, said Roth. The drug, which is usually taken orally, is also the least expensive antibacterial treatment available and has the fewest side effects, he said.

Benzoyl peroxide is an effective antibiotic when applied to the skin as a gel, Roth said, especially in combination with Ret A.

Antibiotics are ineffective in treating severe acne, said Roth, because the inflamed pimples have gone beyond the involvement of bacteria. In this case, the use of steriods, either taken orally or injected into acne cysts, can help reduce inflammation, he said.

Hormones are also an effective acne treatment, said Roth. Estrogen causes a decrease in the formation of fats by the sebaceous gland.

Roth said acne treatment can sometimes be combined with birth control, as long as the pill contains enough estrogen. Some pills contain progesterone, a hormone which may make the acne worse.

Roth does not favor this treatment because the effects of long-term estrogen use as yet are unknown.

"None of these treatments are consistently effective for all types of acne without acne surgery," Roth said.

Acne surgery is the removal of whiteheads and blackheads, and the drawing of fluid from papules and cysts. This can be done without scarring, he said, with the use of special instruments.

Ultraviolet light and x-rays are useful peeling agents, Roth said, but don't seem to be effective in ridding the skin of the clumps. Long-term use of these treatments may be dangerous, he said.

"If patients receive enough ionizing radiation they can develop skin cancer 30 years later," he said.

FOR IMMEDIATE RELEASE

STANFORD –

A new technique which may help scientists understand how the visual system works has been developed by Stanford Medical School researchers.

The technique allows scientists to measure the electrical response of the retina to single photons, the particles of which light is composed.

Light is converted by cells in the retina, called photoreceptors, into electrical signals. After processing in the retina, the signals from many photoreceptors travel to the brain where they produce the sensation of vision.

The technique, developed by Dr. Denis Baylor, associate professor of neurobiology, and his colleagues, Drs. King-Wai Yau and Trevor Lamb, was reported in the Sept. 1 issue of *Nature*, a scientific journal.

It involves measuring the electrical signal produced by rod cells, the photoreceptors responsible for vision in dim light, when a single photon of light arrives.

While viewing with a special microscope, Baylor and his associates suck the light-sensitive portion of a single rod cell from a toad retina into a recording electrode. The inner diameter of the electrode is six micrometers, about one-tenth the diameter of a human hair.

They adjust a thin bar of bluish-green light so that only one or a few photons hit the rod and then measure the resulting change in electrical current flowing across the rod's surface.

"We've been able to observe, for the first time, the electrical response of a vertebrate photoreceptor to a single photon," says Baylor. "This should help us to understand several of the processes involved in seeing."

Baylor and his colleagues plan to continue examining the properties of the signals. They hope to get more information about how photoreceptors convert light into electrical signals and how the signals are transferred to the brain.

The work is supported by a grant from the National Eye Institute.

FOR IMMEDIATE RELEASE

STANFORD –

"I'd like a place where we can have a baby safely so we don't have to have it at home."

"I'd like a room with windows so I can have a sense of the passage of time."

"I want a place where a woman who is having a demonstrably normal birth is permitted to make the decisions of how or in what position she gives birth, and who is with her."

These are some of the desires expressed in a forum on alternative birth concepts held at the Stanford Medical Center this week.

The forum, organized by eight Palo Alto women, brought together about 100 parents, nurses, alternate birthing educators, and physicians from the community and the Stanford faculty, to examine the labor and delivery policies at the hospital.

Pat Koenig, spokesperson for the organizers, said Stanford was chosen for the discussion because "we live in this community and Stanford is our community hospital.

"Stanford is a good hospital," she added. "There are creative and progressive people here."

The hospital was represented by a panel including Paul Hofmann, hospital director, Dr. Robert Alway, medical director, Judy Schmidt, R.N., perinatal coordinator, and Barbara Petree, R.N., clinical nursing coordinator for labor and delivery. Dr. Roger Levin, a community internist, acted as forum moderator.

Several people in the audience felt an alternative birth center was needed in the hospital The center would be an area where a woman can labor and deliver in the same room with her partnter present, whwere she can keep her baby close by, and where her other children can visit.

According to Schmidt and Petree, Stanford already offers several alternative birth procedures. These include allowing two persons in the delivery room with the consent of the obstetrician, allowing two persons in the labor room, and allowing labor and delivery in the same room.

The husband can be present during caesarean section except during an emergency.

After birth, the mother and baby can recover together in the same area where labor and delivery took place whenever possible.

Rooming in with the baby is allowed on the postpartum floor of the hospital.

Stanford offers classes in baby care, postpartum self-care, and physical therapy during the period after birth.

Many of the new procedures were implemented Sept. 1 on the recommendation of the Alternate Birth Committee. The Committee operated as a subset of the existing Perinatal Care Committee to "provide modification of traditional practices, maintenance of the integrity of the family unit, and the greatest safety to mother and infant."

(more) 9/14/77 cr

However, lack of space in the hospital so far has restricted alternate birthing to a modification of procedures rather than the establishment of a center, said Petree.

Stanford is a tertiary care hospital. That means it provides a higher level of care and treats patients with more complex diseases than the average hospital. It has a high-risk obstetrical center, and an intensive-care nursery.

The establishment of an alternative birth center at Stanford, said Hofmann, must be viewed in the context of Stanford as a regional care center, with a major proportion of care committed to high-risk cases.

"About 30-40% of deliveries at Stanford are high risk," says Schmidt. "More and more patients are being transported here from other hospitals before delivery so the babies can have as great a chance as possible of survival.

"We have more than an 80% occupancy rate on the postpartum floor. The beds which aren't filled by postpartum patients are usually occupied by postsurgical gynecology patients," she said.

Nevertheless, said Hofmann, "we are looking at the possibility of taking a private room in the postpartum unit" for use in alternative birthing.

"We also have modified our charging structure to reflect the fact that our costs are lower in alternative birthing," he said.

Some forum participants expressed concern that there was no way for them to become involved in changing hospital policies.

Hofmann referred them to their personal physicians for special requests concerning their own delivery.

"Issues regarding changes in policy are reviewed by the perinatal care committee and by members of the obstetrical service," he said.

"Such changes are referred to the medical board, which is the executive committee of the medical staff, and then to the hospital board of directors."

Although only physicians and hospital staff members can sit on the perinatal care committee, Alway said it is free to call on ad hoc consultants for input.

Alway suggested the community provide input to the Health Services Agency for Santa Clara County, in addition to examining hospital policies. The HSA, he said, develops a health service plan for the county and considers requests by hospitals for major changes in existing services.

STANFORD--Dr. Lawrence G. Crowley has been appointed professor of surgery and deputy dean in the Stanford University School of Medicine.

His appointment, announced Wednesday, Sept. 14, by Dr. Clayton Rich, vice president for medical affairs and dean of the medical school, will be effective November 15.

Crowley, 57, is currently professor of surgery and dean of the University of Wisconsin Medical School in Madison.

"Dr. Crowley," Rich said, "has previously distinguished himself as a national leader in academic surgery, as a researcher in the field of oncology, and as a highly effective administrator."

As deputy dean, according to Rich, Dr. Crowley will play a major role in the development of policy and in the administration of the academic programs of the Dean's Office. These include faculty, student and clinical affairs, planning, facilities, budget and research.

Crowley was born in Newark, New Jersey. He is a graduate of Yale University (1941), and of the Yale University School of Medicine (1944).

He was professor of surgery at Stanford, and has served as chief of surgery in its affiliated Palo Alto Veterans Administration Hospital from 1964 to 1972. Prior to joining Stanford, he had been in practice with the Southern California Permanente Group, was in the private practice of surgery as well as having taught and done research at Yale, Southern California and Stanford.

As associate dean for planning at Stanford from 1972 to 1974, Dr. Crowley was responsible for the publication of the Comprehensive Stanford Medical School long range academic plan.

In addition to his administrative responsibilities at Stanford Dr. Crowley will participate in the teaching, research and patient care activities of the Department of Surgery, Rich said.

Dr. Crowley's research has been mainly on the study of hormone-dependent tumors, the management of patients with endocrine-sensitive tumors, and the effects of radiation on function and strength of small intestinal anastomoses.

FOR IMMEDIATE RELEASE
STANFORD –

Inventions produced by medical researchers at Stanford provide an important source of income used to support academic functions.

According to Niels Reimers, manager of the Office of Technology Licensing, license and patent royalty payments exceeded $1 million last year. Most of the money, he said, is used in support of research and "to reduce the ever-increasing cost of education."

Reimers and his associate, John Poitras, are responsible for determining the marketability and patentability of inventions, negotiating licenses, and securing patent rights.

Research comprises a vital part of the University's functions. Within the medical school alone the volume of government-sponsored research was $28.6 million for fiscal year 1976. The University's operating budget for that year was $80 million.

Inventions in medical fields, such as the Optacon reading device, which translates printed matter into the tactile stimuli of Braille code, have had significant impact on medicine and have garnered for the University nationwide attention.

But the benefits of medical research cannot be realized unless inventions make it to market. Since the University is an educational and research institution, it can publicize its inventions, but it can not produce or sell them. The transfer of technology from the clinical laboratory to the marketplace must be done by outside sources such as the government or private industry.

This process is detailed in the current issue of *Stanford MD,* the journal of the Medical Alumni Association.

Government grants constitute a major portion of research development and funding, but actual production is usually handled by industry. The University gives companies the right to make, use, and sell its inventions by granting licenses in return for royalties which are determined as a percentage of sales. Often the negotiated license is exclusive for a period long enough to enable the company to recover its investment.

The Office of Technology Licensing has negotiated nearly 50 agreements for developing and marketing its inventions since its inception in 1970. Six inventions related to the medical field are now produding earned royalties.

For example, Stanford has arranged an exclusive license with the Hewlett-Packard Corporation to develop and produce a coronary care unit (CCU) monitoring system.

This system provides a continuous computerized monitoring of electrocardiograms (ECGs) of up to 16 patients. It analyzes the ECGs and alerts the staff to abnormalities which might endanger the patient. A series of visual and auditory alarms indicate varying degrees of seriousness.

Clinical testing has shown a decrease in the number of abnormal events missed during manual monitoring from 40-60 percent to 15-20 percent.

According to Bill Sanders, cardiology research associate who developed the system, "the CCU system has been enormously successful. More than 110 have been sold since they were first offered in the spring of 1975."

To encourage the investment of capital and equipment by industry, often the University will seek patent rights. Patents provide an additional competitive advantage by ensuring exclusivity in development and production for 17 years.

Patents also provide an additional source of income for the University. Last year patent royalties totaled $300,000.

The government has realized the importance of patents, not only in furthering research but also in protecting its own inventions.

(more)

9/7/77 cr

According to Clive Liston, patent and copyright manager in the University's Sponsored Projects Office, the government's policy is one of "defensive patenting." The SPO is responsible for disclosing inventions to the government and determining the rights and obligations of inventors.

"If diligence isn't observed in reporting its inventions and filing for patents, the same idea could be conceived somewhere else. It could be patented, and the government would have to pay royalties on something they had discovered first," he says.

One result of the government's defensive patenting policy is the institutional agreements which Stanford has with the Department of Health, Education, and Welfare (HEW) and the National Science Foundation. These agreements ensure that Stanford has the first option on any invention which results from agency-supported research.

"HEW has one of the best patent policies," says Reimers. "They really want to see that research gets out."

The strongest earned royalty income source from the Medical Center at present is the fluorescence activated cell sorter (FACS).

Developed in 1971 by Dr. Leonard Herzenberg, professor of genetics, and his associates, the FACS separates cells on the basis of the fluorescent label they carry by passing a liquid stream of cells through a laser beam. The device has been patented, and is used primarily as a research tool.

Patents rarely create monopoly situations. "A good patent stimulates further research," says Reimers. "It is simply one way of accomplishing an objective."

Patents are not suitable for every project. Many inventions are not patented because they would not make enough in royalties to cover the time and expense of filing (an average of $2,000 is now required to file and follow a patent through to issuance) or because they fail to meet patent criteria.

For example, an infant transporter is being developed and produced under license agreement, although it is not patented. Engineered by Dr. Alvin Hackel of the Department of Anesthesia and Pediatrics and Prof. Robert Moffat of the Thermosciences Division of Mechanical Engineering, the transporter provides the increased care and warmth required by newborns during transport.

Patents do not guarantee production. Sometimes a company which has been developing an invention will decide to let its exclusive license lapse, even though the patents on it by then have been secured.

Reimers estimates 1 project in 100 survives the development phase to enter production, and those that do often take years to reach the market.

When industry is reluctant to fund the development of a project, inventors can seek support from the government or go it alone.

After two pharmaceutical firms failed to become interested in their development of a collagen bioimplant material, Dr. John Daniels, assistant professor of oncology, and his partners formed their own corporation.

The bioimplant is a purified and immunogenetically-altered form of collagen, a structural body protein. It is used to correct tissue contour defects such as severe acne scarring. Within days after injection the implant is colonized by cells, vascularized, and becomes living tissue indistinguishable from the skin around it.

Many inventions at Stanford are developed as part of a program of university-government cooperation called the Biomedical Applications Team (BATeam).

The Stanford BATeam is one of four established in 1966 by the National Aeronautics and Space Administration (NASA) specifically to transfer aerospace technology to the solution of biomedical problems.

During the past two years NASA engineers and workers at the Children's Hospital at Stanford have been cooperating in the development of a miniaturized transmitter which can monitor the electromyograms (EMGs) produced by spastic muscles in children with cerebral palsy.

The transmitters pick up the EMG signal from underlying muscles and convert it to radio waves which are relayed to a receiver. Analysis of the EMGs improves the accuracy of diagnosis and increases the success of corrective surgery.

The development of medical technology plays an important role in improving health care. In fact, according to Drs. Robert L. White and James D. Meindl of the University's Institute of Electronics in Medicine, "the quality and availability of health care are becoming increasingly dependent on radically new diagnostic instruments."

But these devices are very expensive, often costing in the tens of thousands of dollars. The equipment and capital provided by companies like Hewlett-Packard and by government programs like the BATeam make it possible to develop and produce technology which otherwise would be too expensive for the inventor or the University alone to handle.

FOR IMMEDIATE RELEASE
STANFORD –

"The psychological adjustment to a mastectomy takes longer and is much more difficult than physiological recovery," says Dr. Netta Grandstaff, a psychologist in the Department of Family, Community and Preventive Medicine.

Grandstaff and Dr. David Kaplan, director of the Department's division of clinical social work, are conducting a study to develop a more effective coping strategy for breast cancer patients and their families.

The study, supported by a grant from the American Cancer Society, is part of a larger effort by Kaplan to help people deal with serious illness.

Breast cancer is the most common cause of death among women between the ages of 40 and 65. Of the 90,000 new cases of cancer which occur each year, 30,000 women die. One treatment of the disease is mastectomy or surgical removal of the breast. About 110 mastectomies are performed at the Medical Center each year.

Kaplan and Grandstaff have found that about 50 percent of the breast cancer patients they see have problems coping with the surgery.

One goal of the study, says Kaplan, is the identification of maladaptive responses to the discovery of cancer so that counselors can intervene before surgery. Coping problems are treated as if symptoms of an acute disease, requiring immediate care.

This is a departure from the traditional psychoanalytical approach to counseling, says Kaplan. Psychoanalytical counseling involves examinations of the patient's historical background, and treats problems on a more chronic, long-term basis, he says.

Kaplan and Grandstaff utilize problem-solving and decision-making techniques to develop better coping strategies.

"It is inappropriate to use only the psychoanalytical approach for this kind of crisis intervention," says Grandstaff. "Patients need to work on the here and now."

Problem solving involves learning to recognize and deal with the fears and emotions which inevitably arise in crises.

"The way you help people who are facing loss is by so-called grief work," says Kaplan. "You help them to recognize and feel the pain of loss, whether it is a loved one or a part of their body."

Grandstaff counsels patients on a regular basis. Most women she sees have their surgery done at the Medical Center, although she accepts some referrals from outside the Stanford community.

She counsels women and family members or partners together whenever possible. "The most important source of support available to anyone in a crisis situation is the family," she says. "You can't consider the patient alone.

"For instance, the 55-year-old widow who lives alone and has few close friends will have more difficulty adjusting to the surgery than the woman surrounded by a close family."

Often family members have as much or more difficulty than the patient herself, and need counseling too, says Grandstaff.

Today, the woman with breast cancer has more options open to her than she did even three years ago, she says.

"For example, breast reconstruction following mastectomy is now often discussed and planned with the patient by the surgeon and plastic surgeon before breast surgery is performed," she says.

Many mastectomies are performed immediately after the biopsy, particularly if the biopsy is done under general anesthesia in an operating room. But some biopsies are done under local anesthetic on an outpatient basis, and surgery can wait for a few days.

According to Dr. Frank Stockdale, associate professor of oncology, the wait does not seem to effect prognosis.

Grandstaff and Kaplan are trying to determine if the extra time gained between biopsy and surgery helps some patients prepare better for the loss of a breast.

STANFORD--Dr. Paul H. Ward, professor of surgery and chief of the division of head and neck surgery (otolaryngology) at UCLA Medical School, will deliver the second George S. Kiperash Lecture Thursday, September 8.

His talk, "Progress in the Diagnosis and Treatment of Laryngeal Cancer," begins at 8 p.m. in Stanford's Tresidder Union Large Lounge.

The lecture is being presented by the division of otolaryngology of Stanford School of Medicine.

A graduate of Anderson, Ind. College, Ward received his M.D. in 1957 from Johns Hopkins Medical School in Baltimore, Md. He is certified by the American Academy of Ophthalmology and Otolaryngology, and the American Board of Otolaryngology.

Ward had previously served on the staff of the University of Chicago Hospitals and Clinics and at Vanderbilt University Hospital in Nashville, Tenn.

The Kiperash Lecture was established to bring national and international figures to Stanford and to enhance continuing education and residency training.

It is named after George S. Kiperash Jr., a former Stanford patient and native of San Jose. Kiperash is in the ranching business and is associated with Modern Ice and Cold Storage Co. of San Jose.

###

STANFORD--"Health Care Research in Geriatrics" will be discussed by Dr. Jerry Salon on Tuesday, September 6, starting at 4 p.m. in Room M114 at Stanford University School of Medicine.

His address is open to the public.

Until he retired recently, Solon was program planning officer for the National Institute on Aging in Bethesda, Md. His talk is being jointly sponsored by the Department of Family, Community and Preventive Medicine at Stanford Medical School and the Geriatric Research, Education and Clinical Center (GRECC) at Veterans Administration Hospital in Palo Alto.

FOR IMMEDIATE RELEASE

STANFORD –

"The potential for epidemiological research on cancer is greater in China than nearly anywhere else in the world," according to Dr. Henry S. Kaplan, D'Ambrogio professor of radiology at Stanford University Medical Center.

The study of the incidence, distribution, and control of cancer in the vast population of that country could offer clues to the causes of various forms of the disease, he said in a Medical School lecture Oct. 20.

Kaplan recently led a U.S. cancer delegation to China to learn about cancer research, diagnosis, and treatment there.

The group, which included radiation therapists, chemotherapists, immunologists, surgeons, pathologists, and epidemiologists, was part of a cultural and scientific exchange program sponsored by the Committee on Scholarly Communication with People's Republic of China.

The highest incidence of oral, or nasopharyngeal, cancer (NPC) in the world is found in Chung Shan County in Southern China, said Kaplan. NCPs are cancers which involve the nasal cavity and upper throat.

The incidence of NPC in Chung Shan is 14.7 per 100,000 population, Chinese officials told Kaplan. The mortality rate is 12.5 per 100,000.

One cause for this high rate of cancer may be air pollution, said Kaplan. "There are no chimneys in the homes of peasants in Southern China," he said. "The soot from kitchen fires is deposited on the walls."

Pigs, which are often kept in stalls in the kitchen, also show signs of NPC. However, Kaplan said, men, who do very little of the cooking, are afflicted by the disease two and a half times more than women.

The highest incidence of esophageal cancer in the world is found in Linhsien County in North Central China, said Kaplan. The incidence rate, 139 per 100,000, is higher than the incidence for all types of cancer in Shanghai, a city of 12 million people. The death rate from esophageal cancer in Linhsien is 127 per 100,000.

The high incidence of this cancer may be related to a mulch of vegetables which is commonly eaten by people in the region after it has been allowed to sit and grow a cover of mold, said Kaplan.

(more)

The mulch is very acidic. Acidic conditions permit conversion of the high levels of nitrates and amines found in the soil and water of Linhsien into nitrosamines, which are potent cancer-causing agents in rats, he said.

Officials in China told Kaplan that few studies were being done on the relation of occupational factors to these cancers.

Early diagnosis of esophageal cancer is done in China by having patients swallow a mesh-wrapped balloon and then pulling it back through the throat. The mesh scrapes mucous membrane off the esophagus which then is examined under the microscope for the presence of cancer cells.

Early diagnosis of liver cancer, which has the third highest cancer incidence in Shanghai, is done with a radioimmune assay, said Kaplan. The assay measures the level of protein markers in the blood which are secreted by immature cancer cells in the liver. The assay is also used to monitor the response of patients to surgery.

Twenty years ago China had only one cancer hospital, said Kaplan. Now it has five, and six more are in construction.

Each hospital in China has two pharmacies, said Kaplan. One dispenses Western medicine and the other Chinese herbal medicine. Herbal medicine is used with other forms of therapy, and alone when other treatments have failed, he said.

"Chinese surgery is very impressive," said Kaplan. "The surgeons are first-class and their training is excellent."

Acupuncture is used as anesthetia prior to the surgical removal of tumors, but only very selectively, said Kaplan. Western anesthetics are employed, but the Chinese clinicians don't like to use inhalation anesthesia, he said.

The study group found that much of the radiology equipment was about 20 years old, and that radiotherapy clinics were often cramped.

However, one clinic treated 555 patients every 24 hours, in four rotating shifts, said Kaplan. In comparison, Stanford treats an average of 120 patients a day with radiation therapy.

For the treatment of lymphomas, the eighth most common cancer in China, no lymphangiography or laparotomy is performed, said Kaplan. These x-ray and surgical techniques are used in the US to stage, or determine, the precise location of the tumor in the lymphatic system and the extent of its spread to other parts of the body.

Kaplan attributes the poor survival rate in patients with lymphomas in China to inadequate diagnosis and staging prior to treatment.

STANFORD--Dr. Lawrence G. Crowley has been appointed chief of staff of the Stanford University Hospital and Clinics, it was announced Thursday, October 20.

Crowley, currently dean of the University of Wisconsin Medical School, will return to Stanford on November 18 as deputy dean of the School of Medicine. He will hold both positions.

Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine, said the chief of staff will work closely with the faculty and community members of the Medical Staff and with the clinical practice in the Hospital.

"It is our intention to bring a considerably greater emphasis to Medical Staff affairs," said Dr. Rich.

He also indicated that the responsibilities of the chief of staff and of medical director of the hospital and clinics will be combined.

Present medical director of the Stanford University Hospital is Dr. Robert H. Alway, professor of pediatrics. He will become professor emeritus at the end of the year.

###

STANFORD--Conrad F. Gullixson, Palo Alto attorney, has been named new president of the Board of Directors of Stanford University Hospital.

Frank H. Roberts of Palo Alto served as president of the board since 1971, and will continue to serve as a member of the board.

Dr. Alejandro Zaffaroni of Atherton was reappointed as vice president of the board, and John Santana, Jr. of Palo Alto will continue to serve as secretary-treasurer.

Others reappointed to the nine-member board are Dr. Edward L. Ginzton, Kenneth R. Hansen, both of Los Altos Hills; Carroll J. Rousch of Portola Valley; Mrs. O. Meredith Wilson of Palo Alto; and Dr. Clayton Rich, vice president for medical affairs and dean of the school of medicine.

The board members were reappointed by the Trustees of the University at their October meeting.

FOR IMMEDIATE RELEASE

STANFORD –

The Psychiatric Clinical Research Center at Stanford has been awarded a two-year $500,940 grant by the National Institute of Mental Health (NIMH) to study the biological correlates of mental illness.

The Center, which is administered by the Department of Psychiatry and located in the Palo Alto Veterans Administration Hospital, will investigate various kinds of hormonal and neurochemical changes associated with depression and schizophrenia.

Stanford is one of eight psychiatric research centers now funded by the NIMH. The others include centers at the University of California at Los Angeles, San Francisco, and San Diego; Camarillo State Hospital in California, the University of Chicago, the University of Pittsburgh, and Yale University.

The grants provide funds for expanding already existing centers and for establishing new centers "for the conduct of clinical and laboratory research on scientific questions concerning severe mental disorders by scientists of different disciplines."

Stanford's Psychiatric Clinical Research Center (CRC) was established by the Department of Psychiatry in 1973 under the direction of Dr. Philip Berger, assistant professor of psychiatry and behavioral sciences.

In July 1974 the CRC moved to its present facilities in the VA Hospital. The 12-bed inpatient unit generally carries a patient load of 8-10 and is staffed by four physicians.

The grant will enable the CRC to enlarge its staff and increase both its research and the time devoted to patient care, says Berger, who is the principal investigator.

"The organizing principle for the CRC is that an interaction between environment, or the events of life, and brain biochemistry is responsible for mental illness," he says.

In addition to environmental factors, says Berger, researchers have found roughly two dozen chemicals in the brain which may affect behavior. These chemicals include neurotransmitters, which relay electrical signals between nerve cells, as well as factors which modify their action.

"We know very little about them," he says. "Any of them may play a role in mental disorders."

The CRC will analyze the biological fluids (blood, urine and spinal fluid) of patients to see if levels of these chemicals are related to their illnesses, says Berger.

Center researchers hope to identify mental illness in terms of both its biochemistry and clinical symptoms. This will aid physicians in predicting the response of patients to drugs and the outcome of treatment, he says.

"The ultimate goal of our unit is to find more effective and safer treatments for hospitalized patients with severe mental diseases such as depression and schizophrenia," says Berger.

FOR IMMEDIATE RELEASE
STANFORD –

A Stanford University report on government relations warns that the regulation of academic medical centers may be the precursor of much deeper and more pervasive controls to come affecting the entire university.

Increased concerns for safety, cost containment, protection of human subjects, and pressures to broaden the scope of medical education have produced tangible benefits, but also a costly regulatory nightmare for the Medical Center, according to the report.

"We are not conjuring up nightmare visions or parading fears about a remote future," the report says. "In the world of the Medical Center the future that concerns us is here and more is coming.

"The University must attend to what is happening to one of its parts."

The study is part of a scrutiny of the relationships of the Stanford University Medical Center and the government. It was conducted for the Sloan Commission on the government and Higher Education. Coauthors of the report are Robert Rosenzweig, vice president for public affairs, Christopher Wilkes and Nancy Freedman.

The Medical Center was chosen for the study, Rosenzweig wrote, because it "is both a kind of a university in its own right and something else that universities typically are not—a purveyor of a consumer service of enormous public importance.

"That combination makes it the object of the social forces that affect the main institution, as well as its unique role as supplier of health care to the public.

"In every department we studied, we found increases in personnel and other costs in order to anticipate, interpret and comply with government rules. Some entire sections—for example, the Center's health planning group—exist for no other reason.

"And it is not too much to say that the need to deal with the government effectively has produced a new subspecialty—the medical lawyer."

Five years ago the Medical Center borrowed half the time of one attorney from the University administration, the report noted. Today the legal department of the Medical Center consists of four lawyers. In addition, malpractice suits are handled by insurance company lawyers, and virtually all other litigation is handled by outside counsel.

The legal department practices what might be best described as "preventive law," the report said. The lawyers' duties fall into four main areas—academic, patient care, general business law, and government regulations.

"The head of the office spends about 75% of his time on evaluating, interpreting and insuring compliance with federal laws and regulations," Rosenzweig said. "He acts as interpreter, advisor and prophet."

Some years ago the relationship of the Medical Center to the government was regarded as a partnership—an important element for the conduct of medical training, research, and patient care, the report said. That relationship has changed.

"It is now the case that the performance of those functions at Stanford and other similar institutions cannot be carried out without the federal government," said Rosenzweig.

"The government now stands, in its various guises, as patron, customer, monitor, regulator, supplicant, seducer, and director. . .in the operations of the modern university medical center," he added.

(more)

The Medical Center, the report said, like the rest of the University, interacts with the government in ways that have little to do with teaching, research, and patient care."

The National Labor Relations Act, the Social Security Act, the Employee Retirement Income Security Act, the Fair Labor Standards Act and a host of others affect medical centers and universities not as specialized institutions, but rather as institutions doing business in an increasingly regulated economy, according to the report.

Yet despite this impressive sweep of federal mandates, the report also notes some positive accomplishments.

"Almost without exception, those to whom we talked spoke of the benefits of the government programs with which they worked," the researchers said. "That is perhaps not surprising in an area like student services, where the benefits of government activity are visible every day in the lives of students.

"It is more surprising in those areas where the interaction is primarily regulatory. Even in those parts of the institution there was a broad recognition of the desirability of regulation and the benefits of altered practices which have resulted from it.

"Better personnel policies, more careful treatment of human subjects in research, improved animal care, tighter financial controls, improved building and operating safety—all of these are seen as healthy results of governmental initiatives."

But the report cautions that it is not easy to strike a balance of pluses and minuses. "If many of the results are in themselves desirable," Rosenzweig said, "the pace at which they come, the costs that accompany them, and the sheer difficulty of managing them are often far less so."

The report cited several examples:

* In the Facilities Department, the unit responsible for the physical plant, an estimated $280,000 is being spent this year attributable to the incremental impact of government. The department has to deal with 32 separate codes—some federal, state, or local—each with its own machinery for enforcement, inspection and reporting.

* Stanford hospital stood to lose $4 million simply by being grouped with Santa Clara County hospitals for purposes of Medicare and Medicaid reimbursements. The hospital is located 500 yards from San Mateo County, and its costs of operation are similar to those of the San Francisco metropolitan area. After lenghty negotiations Stanford was granted exceptional status, and was reimbursed at a higher level. Even so, this mode of classifying hospitals has led to a direct loss to the hospital of $500,000 if pending appeals fail.

* Increasing numbers of Medicare and Medicaid patients have exacerbated the natural increase in paper work. The gap between public and private levels of health care reimbursement is also increasing. At present this gap is 18%. Since federally funded patients at Stanford now constitute 40% of the patient load, this gap represents considerable and direct cost to the hospital.

* In personnel, about 25% of staff activity relates to compliance with federal regulations. About 750-man hours have been added and $100,000 spent just for implementing the Employee Retirement Income Security Act of 1974.

* The Health Professions Educational Assistance Act of 1976 requires medical schools to waive their own academic standards in order to admit American students enrolled in schools abroad. The law is in effect for three years, and any school refusing to accept this provision will lose its educational subsidies. The Medical School stands to lose $410,000 in federal support if current bills to amend the law fail to pass.

"In part, such problems arise from the sheer size and clumsiness of the federal establishment," Rosenzweig said. "In further part, however, they are the product of the process by which such rules are devised.

"That process consists of organized and articulate groups pressing for the redress of a perceived injustice. Their force, both political and moral, frequently overwhelms such complications as questions of timing, the capacity of institutions to respond and the relationship among problems and the remedies.

"All such questions tend to be seen merely as excuses for delay. But if justice delayed is justice not done, it is also true that both the cause of justice and of the institutions that must be the instruments of justice can be undone by thoughtless haste.

"Somehow, the process of policy-making must balance both of those truths better than they have done so far."

STANFORD--A comprehensive treatment program for persons concerned about their alcohol use is now available through the new Alcohol Clinic at Stanford University School of Medicine.

The clinic offers a wide range of outpatient services for alcholics and their families, including comprehensive diagnostic procedures, individual counseling and psychotherapy, group therapy, sexual counseling, family therapy and childrens' services. In addition, an education program is offered to all patients.

The clinic services focus on living problems and emotional difficulties, as well as specific problems patients have with alcohol, according to Stephanie Brown, Ph.D., associate director of the clinic.

Brown says that people concerned about their own alcohol intake or that of a family member, may call the clinic directly for referral to the program. Once patients have called, a series of interviews are arranged, including detailed clinical assessment, psychological testing, and medical evaluation, if necessary. Once these are completed a specific treatment plan, appropriate to each individual, is drawn up by a team of professionals.

The Stanford Alcohol Clinic, which is directed by Dr. Irvin D. Yalom, professor of psychiatry and behavioral sciences, also encourages patients to use Alcoholics Anonymous (AA) and other resources.

STANFORD--Dr. Clayton Rich has been named the Carl and Elizabeth Naumann Professor and Dean of the School of Medicine.

Rich is the first holder of the new chair. It was endowed by gifts from Mr. and Mrs. Carl Naumann of Beverly Hills. Mrs. Naumann attended Stanford and received her A.B. in philosophy in 1919.

This is the third endowed deanship at Stanford and the first in the medical school.

"The designation of Dr. Rich is a most fitting recognition of his significant contributions to the University," said the announcement from the Board of Trustees. "He has guided the continuing development of the academic program of the school with remarkable success."

Rich has been vice-president for medical affairs and dean of the medical school at Stanford since 1971. He is responsible for the planning and construction of the new Sherman Fairchild Center and other key facilities designed to strengthen the basic and clinical sciences. Last year in a study of 87 medical schools, Stanford ranked among the top three in the United States.

He also has become nationally known for his leadership in questioning the widening intrusion of federal bureaucracy into academic-decision making.

A graduate of Cornell, Rich became an established teacher, administrator and researcher in clinical medicine. He specialized in endocrinology and has conducted his principal work in the areas of calcium metabolism and bone mineralization.

Prior to coming to Stanford, Rich was professor of medicine and associate dean for clinical affairs at the University of Washington School of Medicine in Seattle.

TWO STORIES: Barbara Battino, 497-6911
Marcia Tanner, 497-3812

FOR IMMEDIATE RELEASE

STANFORD –

Dr. Paul A. Ebert, renowed cardiac surgeon, professor and chairman of surgery at UC Medical Center in San Francisco, will present the eighth Louis and Dorothy Kovits visiting professorship lecture at Stanford School of Medicine Tuesday, Oct. 25.

Dr. Ebert will speak at 4:30 p.m. in the Fairchild Auditorium of the Medical School. His topic will be the pathophysiology of pulmonary embolus, the methods of treatment and role of surgery in patients with long-standing pulmonary artery occlusions.

Physicians and other health professionals in the community are invited to attend.

Dr. Ebert is a well-known pediatric cardiac surgeon. He successfully developed the technique for connecting the pulmonary artery with the right ventricle of the heart in infants less than six months old.

Prior to joining UCSF in 1975, he was professor and chairman of surgery at Cornell University Medical College. He received his M.D. degree from Ohio State University in 1958, and holds several awards, including Johnson & Johnson Professor at Cornell in 1972, and Markle Scholar at Duke University Medical Center in 1967.

The Kovitz lectureship was established in 1969 by Dr. and Mrs. Kovitz of Los Angeles to bring outstanding lecturers in medical and surgical fields to the Medical Center.

STANFORD –

Visiting Prof. Dr. Walter Ducloux will lecture on Verdi's grand opera "Aida" in the last of his "Exploring Opera" series at 4:15 p.m. Thursday, October 27, in the Large Lounge at Tresidder Memorial Union.

Tickets for this lecture are $2 general, $1 for students.

"Exploring Opera" is the first in a series of public lectures to be sponsored by the Music Guild at Stanford. Proceeds support lesson scholarships for Stanford music students.

SCIENCE WRITERS: This story is released in conjunction with the presentation of a scientific report at the International Congress of Dermatology October 20 in Mexico City. Photo available on request if not included with story.

ADVANCE FOR PM RELEASE THURSDAY, OCTOBER 20, 1977.

STANFORD –

Fat-producing cells in the skin which are involved in the development of acne have been successfully grown outside the body for the first time by a Stanford researcher.

Isolated sebaceous gland cells may provide important information about how abnormalities in the glands result in acne, said Dr. Marvin A. Karasek, associate professor of biochemistry in the Department of Dermatology.

Karasek presented his findings Thursday, Oct. 20, at the International Congress of Dermatology in Mexico City.

The function of the sebaceous glands in humans is not known, said Karasek. Other researches think that abnormalities in fat production by the glands may cause acne.

Karasek isolates sebaceous glands from extra tissue obtained from patients who have undergone plastic surgery, and from the ears of rabbits. He separates the glands from surrounding tissue by exposing it to an enzyme which breaks down proteins.

The glands are grown on collagen gels using standard growth media.

The difficulty in the technique, said Karasek, is isolating glands under gentle conditions very rapidly so that they remain viable.

The cultured gland cells retain their ability to synthesize and accumulate fats in patterns similar to the intact gland, he said. But they respond differently to some hormones.

Estrogen, a circulating sex hormone, inhibits fat production by sebaceous glands in the body. However, it stimulates production among isolated gland cells. Karasek doesn't know why there is a difference between cells in the body and in culture.

"The clinical applications of this study may be very large," he said.

"When we know the details of the biochemistry of the glands, we can begin to look for methods of controlling fat production and gland cell growth."

Karasek eventually wants to look for differences between the sebaceous glands of "normal" subjects and those with acne.

"We'd also like to see if the serum from patients with acne accelerates fat production in normal isolated glands," he said. Hormones may play a role in the development of acne, he said.

FOR IMMEDIATE RELEASE

STANFORD –

Stanford University School of Medicine is moving rapidly into a new field—the comprehensive treatment of babies before they are born.

The new program is spearheaded by Dr. W. Leroy Heinrichs, a tall 45-year-old Oklahoman who became chairman of the Department of Gynecology and Obstetrics last year.

"The risks of dying once one is born never are as great as during birth—until one is 85 years old," says Heinrichs, who joined Stanford from the University of Washington in Seattle.

He says that in the last 10 years, a number of dramatic advances have revolutionized the science of birth. There are new medications, obstetrical methods, new clinical apparatus, and diagnostic tools.

Medicine, Heinrichs feels, is now challenged to regard the unborn fetus as a patient and to get to work curing its ills.

By such progress, he says, a disturbing lack of progress in reducing infant mortality may be corrected. In the future, he predicts, care of the fetus will rest with obstetric-pediatric teams assisted by biomedical engineers. Stanford is especially suited for this research role because of its programs in engineering and medicine.

Several techniques to monitor the well-being of the fetus are currently utilized in Stanford's High Risk Clinic.

For instance, physicians can detect birth defects, sex, and the maturity of lungs of the unborn baby by examining fluid taken from the womb. This procedure is called amniocentesis.

Ultrasound aids in locating the position of the fetus, measuring its heart beat, and estimating its size and age.

Physicians measure changes in the heart rate of the fetus when it is stressed by uterine contractions. A decreased heart rate indicates fetal distress.

During delivery the heart rate of the baby is monitored by placing a scalp electrode under the skin of its head. Blood is drawn from the fetus in some cases to see if it is tolerating labor well.

Most of the babies born in the U.S. each year arrive in bouncing good health, but some 30,000 babies get sick in their mother's wombs, or die before they are born.

Heinrichs is critical of the current trend in home birthing because of the risk of problems arising during delivery.

The danger of home delivery, he says, is the "risk that only can be identified as the baby moves through the birth canal. Home deliveries aren't geared to watch for this."

It is the job of the obstetrician, he says, to identify these risks and prevent their impact.

Heinrichs has made three recent appointments he hopes will strengthen Stanford's role in perinatal medicine.

All of the new appointees are specialists in the care of the fetus during pregnancy and at the time of birth.

Dr. Kent Ueland, from the University of Washington in Seattle, this month was appointed professor of gynecology and obstetrics and director of the section of maternal-fetal medicine. He is researching chemical means to prevent premature labor.

Dr. Paul A Hensleigh, associate professor from the University of Kansas in Kansas City, is testing biochemical methods of evaluating the maturity and well-being of the fetus during pregnancy.

Dr. W. Desmond McCallum, assistant professor from the University of Washington, is using ultrasound techniques to measure fetal blood flow. measure fetal blood flow.

"Currently there are not too many good methods of measuring fetal well-being," says McCallum, who received both medical and research degrees from The Queen's University of Belfast, Northern Ireland, before coming to Seattle.

McCallum has been working on estimations of fetal blood flow and velocity for the past few years.

He is now developing computer methods to measure fetal-placental blood dynamics by analyzing Doppler ultrasound signals.

Doppler ultrasound projects a low-energy beam of sound through the abdominal wall of the mother at cardiovascular structures such as the umbilical blood vessel. Part of the beam is reflected back, but at a different frequency depending on the velocity of blood in the vessel. The change in frequency is called the Doppler effect.

(more) 10/13/77 cr

McCallum hopes this method will provide a more detailed record of the fetal heart than present techniques.

Hensleigh has been involved in the evaluation of placental compromise. Compromise refers to a decrease in the blood flow through the uterus and placenta to the fetus which may result in fetal malnourishment and sometimes intrauterine death.

Hensleigh tested the blood of women suffering from hypertension during their pregnancies. He measured the levels of a hormone produced by the placenta and an enzyme thought to aid protein transport from mother to fetus.

Hypertension is often associated with retardation of fetal growth, he says. Low serum levels of the hormone or enzyme could indicate placental compromise.

He found that 75% of babies born malnourished would have been predicted by the test.

According to Hensleigh, these tests are less cumbersome and time-consuming than other methods of monitoring placental function.

His latest interest is measuring the amount of heat which is dissipated by the fetus through the mother.

"Any living fetus is warmer than its mother," he says. "The only way to rid itself of metabolic heat is through her."

Initial studies with sheep indicate a correlation between changes in temperature and uterine blood flow. If the flow is constricted, the temperature of the fetus rises in seconds. This shows the fetus is retaining its heat, he says.

Hensleigh hopes to be able to relate uterine blood flow to effects on fetal functions such as heart rate.

Ueland is well-known for his work on cardiovascular changes in women during pregnancy. He and Dr. James Metcalfe at the University of Oregon found that cardiac output, heart rate and blood volume changed significantly during pregnancy and at delivery, and related these factors to heart disease.

Recently, Ueland has been evaluating ritodrine, a drug used to prevent premature labor.

Ueland says the drug appears to be very successful in preventing uterine contractions so far in clinical tests. He will continue his studies at Stanford.

"The leading cause of perinatal death in the world is prematurity," he says. "If we can stop the premature deliveries which need to be stopped we can cut perinatal mortality significantly.

"But the biggest dilemma now facing us is knowing which premature labors to stop. At least one third of all early labors are triggered by underlying causes, such as the partial separation of the placenta or an infection, and should not be stopped."

Ueland, who received his medical degree from the University of Illinois in Chicago, has spent 17 years at the University of Washington. There he served as professor of gynecology and obstetrics, and established and directed the division of maternal-fetal medicine.

Heinrichs' own research is in the physiology, biochemistry, and metabolism of sex hormones. Most recently he has been investigating how hormones produced by the fetus before birth determine the regulation of metabolism in adulthood.

For example, Heinrichs and his associates have studied biochemical and hormonal changes and abnormal development in animals exposed to DDT immediately after birth.

In addition to research, the department is supporting the establishment of a regional perinatal project, with two high-risk obstetric referral units, one at Stanford and one at Santa Clara Valley Medical Center in San Jose. Funds for the project have been requested from the California State Department of Health.

The high risk centers would be responsible for assessing maternal and fetal care, research to improve education and management of high-risk atients, and education of professionals in the region, says Hensleigh.

Hensleigh was involved in the development of a statewide perinatal care program in Kansas.

Perinatal deaths in Kansas dropped from a relatively constant figure of 24 deaths per 1,000 in 1974, when the program began, to 15 in 1976, says Hensleigh. California had 18.8 perinatal deaths per 1,000 in 1975, close to the national average, he says.

"In general the institution of regional programs is associated with a reduction in perinatal mortality of 30-40% over two to three years," he says.

The reduction in deaths is due mainly to the way physicians handle complications in pregnant and newborn patients, says Hensleigh, recognizing problems, seeking consultation without hesitation, and referring severely ill patients to the appropriate facilities.

"Emphasis is on the transport of the mother rather than the baby," says Hensleigh. "The outcome is better when the baby is delivered in an institution with optimal neonatal care."

Barbara Battino

[redacted] or Andreopoulos

STANFORD -- Stanford University officials said Wednesday they are confident the medical practice system at the School of Medicine conforms with state law.

The statement was issued by Spyros Andreopoulos, public information officer, in response to allegations made yesterday by the Union of American Physicians (UAP).

The UAP charged that Stanford is in violation of California State Law, section 2008 of the Business Code, by charging patients for medical services performed by physicians on the medical center staff.

"The charge presents nothing new to the suggestions made in past years by others that all medical services provided in teaching institutions be rendered free," said Andreopoulos.

"As in past statements," he said, "the university reiterates its position that it uses the same system as most medical schools.

"This system is in full compliance with all laws and is even routinely evaluated by federal and state agencies."

Andreopoulos said the medical center is subjected to routine audits by governmental agencies. Professional fee billings [redacted] must conform to standards established by these agencies.

FOR IMMEDIATE RELEASE

STANFORD –

Victims of accidents or heart attacks in the Bay Area no longer have to wait until they get to the hospital before receiving emergency medical care.

Now they can receive treatment at the scene from paramedics trained by the Stanford Hospital.

"I think the paramedics are the best thing that has happened in our community in a long time," says Bill Korff, chief of the Palo Alto Fire Department, which now has 15 certified paramedics.

"We were aware of the need for something like this for a long time. We'd go to the scene of an accident and be frustrated that we couldn't help very much," says Korff, who helped organize Palo Alto's paramedic program.

The paramedic training program at Stanford Hospital is the only regionwide program in the Bay Area. Paramedics from Palo Alto, San Jose, South San Francisco, and East Bay communities have participated in the program. One Stanford-trained paremedic works for the National Park Service at Yosemite National Park.

Dr. Michael Eliastam, director of Emergency Services, heads the program, which has graduated 150 persons since it began in 1973.

Paramedic students receive six weeks of classroom training from Stanford instructors and local physicians in the communities where they are expected to work.

Students learn the characteristics and field treatment of common problems they will encounter, including the collapsed and unconscious patient, major burns, severe emotional disturbances, major trauma, and cardiac problems.

They then receive four weeks of training in community hospitals and six weeks of field training. During this time they practice administering medications, perform venipuncture, initiate intravenous therapy, carry out airway management, participate in cardiopulmonary resuscitation (CPR), apply dressings and slints, perform defibrillation, and allocate treatment among patients in a mass disaster situation (triage).

Once the students have completed the program they must be certified by the public health officer in the county where they intend to work.

(more)

10/11/77 cr

paramedics 2- 2- 2-

Paramedics always deliver emergency care under the radio supervision of a physician or a certified mobile intensive care nurse (MICN). The MICNs have been specially trained in radio communication and specific problems that paramedics encounter.

MICN nurses in Santa Clara County must have at least six months experience as RNs in the emergency department and must be certified in Advanced Cardiac Life Support.

They also must accompany paramedics on at least six field trips, to get a better idea of what can and cannot be done in the field.

"If someone is trapped in an automobile wreck and the MICN tells the paramedic to start an IV line and after a minutes or so starts yelling at him for not getting it started, she isn't helping him," says Barbara Behrens, RNs, who directs the Stanford MICN training program.

"The nurse needs to realize that the paramedic may be trying to work through a window that's only slightly open or may be trying to pry the car's door open. She can only appreciate this if she actually has gone to the scene of an accident."

Perhaps the greatest difficulty for the MICN or physician in the emergency department is having someone else be their eyes and ears, says Behrens. Eliastam hopes eventually for a method of transmitting a television picture of the patient from the scene to the hospital.

People who need emergency medical care should dial the emergency telephone number in their area. In Palo Alto the number is 911.

"It doesn't do any good to have paramedics if you don't know how to get help," says Charlene Souza, RN, paramedic training program coordinator at Stanford.

Dialing the operator is not the right thing to do, she says. If you are calling from Palo Alto, you could be connected with an operator in Oakland, who has no idea of available medical services in Palo Alto.

Within two minutes of receiving a call, says Korff, a fire engine is at the scene and firefighters trained as Emergency Medical Technicians (EMTs) begin life-saving procedures. The EMTs have had 100 hours of training in basic life support. Paramedics arrive 2-4 minutes later.

According to Souza, there are no figures which reflect the impact of paramedics on emergency medical care in Palo Alto. However, in Seattle, which has perhaps the nation's most comprehensive emergency medical system, 655 almost clinically dead people were saved in the past six years. This high figure, says Souza, reflects the early CPR given in emergency situations by many citizens, as well as medical personnel.

FOR IMMEDIATE RELEASE
STANFORD –

Dr. Robert H. Alway, medical director of Stanford Hospital and former dean of the Medical School, recently announced his retirement, effective Dec. 31.

Alway, whose mission it was to move the Medical School from San Francisco to the Palo Alto campus during his term as dean, ends a 26-year association with the School..

During his years at Stanford, although one critic accused him of having no ceremonial front, he nonetheless earned the admiration of those who worked with him.

A native of Nebraska, Alway took his undergraduate degree, an M.B. and M.D. all at the University of Minnesota. He interned at Jersey City Medical Center and was pediatric fellow and resident at the University of Minnesota from 1940-43.

Alway taught at the University of Utah Medical School before coming to Stanford in 1949. Four years later Xhe accepted a position as head of the pediatrics department at the University of Colorado. After two years he returned to Stanford to head its pediatric department.

At this time the University was attempting to resolve conflicts over the planned move of the Medical School from its century-old dwellings in San Francisco to Palo Alto.

Many faculty members did not want to leave the San Francisco area, and Lower Peninsula physicians feared the move would intrude in the care of their patients.

"We were as cursed for leaving as we were generally unwelcome down here," says Alway.

The new Medical School had to find new sources of patients to satisfy its teaching requirements. To do that it had to cooperate with community physicians and develop contacts with agencies, hospitals, and resources in the area.

In fall 1956, the late Windsor Cutting resigned as dean of the Medical School. Alway accepted the deanship, first in an acting capacity, and then full-time in spring 1958.

When Alway took the job, Stanford President J.E. Wallace Sterling made it clear that the department heads were expected to resign to leave a clean slate for the new dean. They did, and Alway began his six-year leadership of a moving and building medical school.

Alway's small office in the Hospital is graced by one 8 X 10 black and white photograph of the old Medical School in San Francisco. It seems to signify that singular goal which has characterized much of Alway's professional life, bringing medical education into the realm of the humanities.

Alway shares the conviction that "the physicians for the future must work in an environment strengthened by the humanities, the social sciences, and the natural sciences."

This is what he hoped the move would attain, an increase "in the breadth and effectiveness of medical teaching and education."

One of Alway's first acts after the new Medical School opened in 1959 was the appointment of top scientists to department head positions.

Nobel prize winner Joshua Lederberg from the University of Wisconsin became the chairman of the newly established department of genetics. Dr. Arthur Kornberg, who received his Nobel Prize in 1959, was appointed chairman of the biochemistry department, and brought with him several members from his department at Washington University in St. Louis. Dr. Norman Kretchmer came from Cornell University to head the pediatrics department.

At the same time Alway was cultivating contacts with the Palo Alto medical community to orient it to the needs of the Medical School. By the end of his term as dean the patient load at the School had risen, and had satisfied many of the requirements of undergraduate clinical teaching.

Under Alway's leadership the faculty size doubled. Three new departments, genetics, anesthesia, and dermatology were created. Research funds were tripled.

Stanford received funds from the National Institutes of Health in 1962 for the establishment of the first clinical research center for premature infants in the U.S. Among the research programs which developed at this time were those in radiotherapy and organ transplantation.

— more —

Alway is the first to deny sole responsibility for the success of the move to Palo Alto.

"I didn't do these things," he says. "I was blessed with a rabbit's foot, and a superior faculty.

"The reputation which Stanford was rapidly expanding through President Sterling and Provost Terman and many others certainly didn't hurt us in attracting faculty and, even more so, in attracting a quality of student body which was clearly superior, and continues to be so."

During Alway's term the Medical School experimented with a special five-year curriculum which combined University and Medical School courses.

"Students could complete their baccalaureate requirements in their first three years while at the same time getting under way with the basic science studies in the Medical School," says Alway.

Some students took advanced degrees in other fields, such as anthropology. Others did basic medical research. And some combined their medical studies with electives in music or poetry.

"The faculty hoped to achieve the development of an introduction to clinical medicine which would combine most effectively the capacity for communication, caring, and curing," says Alway.

The program was later discontinued for financial reasons, but concern for the humanistic element in medical education has remained, says Alway.

"I often congratulated entering classes on beginning a physician's career, and expressed hope that some of them would also become doctors," he says with a wry smile. "In the original usage, doctor meant learned person and teacher."

Alway resigned as dean in fall 1964. In a memo to the department heads he said, "Without you and each member of the Medical School faculty, the School would not have the national prominence it now enjoys."

He again took up the duties of a professor of pediatrics, but this wasn't the end of his administrative role at Stanford.

In 1975 Alway was appointed medical director of the Hospital and associate dean for clinical affairs. He also became a member of the regional Medical Quality Review Committee serving Santa Clara County, and served on the board of the county Professional Standards Review Organization.

Alway, who has watched the Medical Center grow literally from the ground floor up, sees the next few years as a period of "happy maturation."

Some things the Medical Center does very well, he says, but in other areas it has a long way to go. "That's the nature of a vital and growing place," he says.

The most urgent need at present, he says, is space.

"Our most serious handicap is the lack of space to comfortably and effectively cope with even the present demands.

"Government controls, controls on remodeling and building, and on the availability of funding all loom large in holding back the speedy and effective meeting of these needs," he says.

Medical education in the next few years will feel the weight of a movement for the production of family practitioners, he says.

Alway is cautious in his support of holistic medicine, while recognizing unmet needs for primary care.

He has always stressed the need for humanism in the practice of medicine. "Much of what gives us dis-ease and even a good deal of disease requires at least as much psychosocial support as physiological."

But he feels society must carefully evaluate the roles that deliverers of primary care can play in medicine, and determine how resources will be allocated between the nurse-practitioner and the physician.

Alway's immediate plans include retiring to a new home on the San Juan Islands, north of Seattle, Washington. There, with his wife, he will "devote as much time as is necessary to permit sedimentation, allowing again more clear vision.

"You know computers blow out their fuses sometimes. Well, I think I have input overload," he says.

For Alway, who manages to combine the friendly faced general practitioner with the tough administrator who minces few words, retirement is not an end to work, but R and R, preparing him for his next mission in life.

STANFORD –

Sleep therapy and acupuncture to control itching, lasers to remove skin tumors and tatoos, and fasting to treat psoriasis are some of the innovative treatments for skin disorders used in the Soviet Union.

Dr. Eugene M. Farber, director of the Department of Dermatology at Stanford, observed these techniques in several Moscow clinics and hospitals during a recent visit.

Farber's trip was part of the U.S.-Soviet Cooperative Program in Health. The program, designed to exchange scientific information between the two countries, is administered in the U.S. by the Department of Health, Education and Welfare, the Public Health Service, and the National Institutes of Health.

Farber was the first American dermatologist to participate in the program.

The Soviets are acquainted with the current PUVA photochemotherapy for psoriasis which is being clinically tested in the U.S., says Farber, and they are planning to evaluate it.

PUVA stands for psoralen, a drug which sensitizes the skin to light and ultraviolet light. The combination of drug and light treatment appears to slow down and break up the disease process. Stanford is one of 16 U.S. medical centers conducting clinical trials on the photochemotherapy.

Soviet physicians use some therapies which rely less on drugs than those in the U.S., says Farber.

Patients with itching problems are sometimes put to sleep with low fequency sound waves transmitted through a helmet they wear, he says. This is called electrotherapy.

The patients fall asleep within 10-15 minutes and can remain in that state for hours, he says, although sleep treatments generally last 3-4 hours.

They awaken with no hangover, and the treatment does not interrupt or shorten their usual sleep cycle at night.

Soviet scientists told Farber that the induction of sleep interrupts the itching cycle, and that they prefer this kind of treatment to sedation.

Acupuncture also is being tested as a treatment for itching in the Soviet Union. One researcher believes he has identified the itching center for the entire body, but there is some skepticism about this, says Farber.

Psoriasis has been treated with fasting, says Farber. One professor at the First Medical Institute of Dermatology and Venereal Disease in Moscow put 2,000 psoriasis patients on a diet of mineral water and vitamins for two weeks. The patients also received daily enemas.

They generally lost 9-10 kilograms (about 20 pounds) and showed some initial improvement, but relapsed shortly after they returned home.

(more)

Dr. Farber feels the improvement was due to lowered protein intake and a reduction in stress during the hospitalization period.

A small portable laser unit is sometimes employed to remove skin tumors and tattoos, says Farber.

Balneotherapy, or bathing parts of the body in water which has been ionized or had oxygen bubbled through it, is used to increase the permeability of the skin to ointments. The therapeutic effect of balneotherapy is nonspecific and partly psychological, he says.

The Russian people suffer from the same diseases we do. However, fungus infections seem to be more common. Soviet scientists attribute this to the widesperead use of antibiotics, he says.

Fungus infection of the finger and toenails is treated with a plaster which dissolves the infected part but not the good part of the nail. "We're just starting to use this here," says Farber.

In another part of the Soviet Union, Farber visited a unique group of people referred to as "long livers." About 15,000 people over the age of 90 live in the Caucasus Mountains of the Soviet Republic of Georgia.

Farber found them to be in good health. Hearing, pulse rate, and memory usually are good. They are alert. They have the skin of 55-65 year olds, he says.

Genetic factors contribute to longevity in this area, says Farber, but social factors such as part-time agricultural work and the closeness of the family unit also are considered to be important by Georgian scientists.

Men in the Soviet Union retire with full pension at age 60 and women at age 55, he says. An Academy of Sciences study on the health of men who retired on pension and who changed environments found that their ability to adapt at age 55-65 was poor. The aging process suddenly accelerated, a phenomenon the researchers call "pension disease."

They also found that among retired people who didn't work, 87% were able to work.

What distinguishes the long livers in Georgia is that they have continued to stay physically active, says Farber.

In addition "they feel needed by their families and society and their families in turn consider them important and necessary to their lives," he says.

The chief of the Gerontology Department of the Academy of Sciences in Tsbilisi, Georgia, told Farber that humans are genetically programmed for 120 years of living.

"But he told me that diet, climate, and physical activity won't make much difference if a person is socially isolated from his family or society," he adds.

Researchers at the Georgia academy found that 90% of the long livers smoke and drink, but in moderation. They are not overweight, but have no special diet. They eat largely what they grow themselves; squash, nuts, grapes, bread, cheese, chicken, boiled lamb, and wines.

They live at 500 to 1,200 meters (1,600 to 4,000 feet) above sea level, and the air is clean, says Farber.

FOR IMMEDIATE RELEASE

STANFORD –

New ways to get patients to take their medicine, finding out how the liver forms cholesterol, and how nerve cells develop—these are some of the topics under study by three young Stanford scientists recently named Andrew W. Mellon Fellows.

The researchers will be supported in part by a $325,000 award to Stanford by the Andrew W. Mellon Foundation of New York. The purpose is "to assist young postdoctoral scholars of demonstrated achievement and exceptional promise to continue their advance toward careers in teaching and research."

The fellows bring to 12 the number of Stanford scientists supported by the three-year award which was given by the Foundation in 1976. The appointments were named recently by Dr. Clayton Rich, vice-president for medical affairs and dean of the school of medicine.

According to the Mellon Foundation, "the chief purpose of the grants is to help minimize the loss to medical education and to research in the basic medical sciences which is certain to occur if individuals. . .are forced by lack of support to turn to other careers."

Stanford is one of 15 private medical schools to receive such funds under the Mellon Foundation Program. A similar three-year grant from the Foundation was given to the University in 1973.

The new Mellon Fellows are Dr. Allen Cooper and Dr. Peter Rudd, assistant professors of medicine, and Bruce Wallace, Ph.D., assistant professor of neurobiology.

Dr. Cooper is studying cholesterol metabolism in isolated livers and intestines of rats.

Cholesterol is a common type of body fat which researchers think may help maintain the structure of most cell membranes.

Cholesterol is produced primarily by the liver and intestine. In particular, the liver is responsible for getting rid of cholesterol and directing its movement through the body, says Cooper.

Defects in the mechanisms which control transport of cholesterol and its deposition in body tissues in man lead to abnormalities such as atherosclerosis, in which cholesterol is deposited in blood vessels. The details of these mechanisms are still unknown.

"If we can understand the basic aspects of how its synthesis and transport are regulated," says Cooper, "we may be able to develop more effective therapies to lower cholesterol levels in the blood."

Dr. Rudd, who came to Stanford, from the University of Chicago Aug. 1, has initiated studies on patient compliance and professional adherence for hypertension.

Recognizing that more than 20 million Americans have high blood pressure, and that most of them either are unaware of their condition or are not taking adequate medication, Rudd believes there is a great need for intervention.

(more)

"There is little use in detecting, evaluating, or prescribing for the disease if patients do not comply with treatment over the many years needed for prevention of hypertensive complications," says Rudd.

"Most professionals are notorious overestimators of their patients' compliance," he says.

Rudd is developing an "optimal" antihypertensive regimen which he hopes will produce better patient compliance and improved clinical outcomes than traditional care.

The regimen is a package of motivational aids such as simplified, once-daily medication. Scheduling, special medication packaging to help patients remember pill-taking, feedback to patients about their past success as compliers, and patient self-monitoring with home blood pressure cuffs.

Rudd will evaluate the cost-effectiveness of each component in the package, and help clinicians implement the improved methods of antihypertensive care.

"To be successful, the package must be relatively inexpensive and readily acceptable to most patients and physicians," he says.

Hypertension is a useful model for other chronic diseases which require daily medication and for which compliance is a problem, says Rudd.

"If we can make a real impact on hypertensive management," he says, "I think many of the lessons can be extended to other diseases."

Dr. Wallace is studying the development of cells in the nervous system of leeches.

The leech lends itself easily to studies of developing neurons, says Wallace, because its central nervous system consists of a chain of identical nerve bundles, or ganglia, each containing 350 cells.

Wallace also is trying to determine how the nerve cells accumulate neurotransmitters during development. Neurotransmitters are the chemical messengers which transport electrical signals across gaps, or synapses, between the cells.

All 12 Mellon Fellows are assistant professors in the Medical School. The nine who retain their fellowship appointments from last year include Dr. Paul Cipriano, radiology; Dr. Leslie Dorfman, neurology; Dr. Donald Goffinet, radiology; Dr. Mark Hilberman, anesthesia; Dr. Paul Pitlick, pediatrics; Dr. David Schurman, surgery; Dr. Gerald Silverberg, surgery; Douglas Wallace, Ph.D. genetics; and Dr. Roger Winkle, medicine.

FOR IMMEDIATE RELEASE
STANFORD –

Research with a protein isolated by Stanford Medical School scientists several years ago is opening the door to better understanding of the development of the nervous system and the regeneration of damaged nerves.

Dr. Eric Shooter, professor of neurobiology, has been working with the protein called nerve growth factor (NGF) since it was isolated in 1967 from the salivary glands of the adult mouse.

Eight years later, in 1975, one of his colleagues, Dr. Alex Wlodawer, successfully crystallized the protein.

Nerve cell growth during development is determined by different signals, says Shooter.

One signal, in the form of an electrical impulse, determines the development of sympathetic and sensory nerve cells. Sympathetic nerves carry messages from the brain to the heart, blood vessels, smooth muscle of various organs, and glands.

NGF provides another signal in the form of a circulating soluble protein, he says.

The presence of NGF in a variety of tissues and species was detected in the early 1950s by an Italian scientist, Dr. Rita Levi-Montalani.

She showed that injection of NGF into nerve ganglia of chicks causes them to balloon up to 12 times their normal size, and stimulates nerve fiber growth tremendously. If antibody to NGF is given to eliminate the factor, growth of the sympathetic nervous system is stopped completely, Shooter says.

NGF is specific for sympathetic and sensory nerves, he says, but it is also found in the central nervous system, including the brain. "We don't yet know what role it plays here," he says.

Once development of the organism is completed, says Shooter, NGF is important in maintaining the viability of the nerve cells whose development it controls.

"It's been known for a long time that nerve cells can sense what's going on in the periphery (at the end organ)," says Shooter. NGF provides information enabling the nerve to make connections with the correct end organs, he says.

Dr. Jack McMahan, newly appointed professor of neurobiology from Harvard University Medical School, has found that the severed muscle nerves of frogs grow back to the muscle, precisely into channels left by the old degenerated nerve fibers.

McMahan believes that some factor may be directing the growth of the nerve to a specific location, although it may not be associated with the target organ itself.

Shooter, with Drs. Keith Hodgson and Julia Goodfellow of the Department of Chemistry, is continuing studies to work out the three-dimensional structure of NGF.

The factor demonstrates certain similarities to insulin, a circulating protein chich facilitates uptake of sugar by cells.

"There is a limited but significant similarity in the amino acid sequence between NGF and insulin," he says. Amino acids are the molecules which make up protein chains.

In addition, Dr. Edward Berger, a member of Shooter's group now at the Worchester Foundation in Massachusetts, has isolated a pro-NGF molecule involved in the biosynthesis of NGF, just as proinsulin is a precursor in the biosynthesis of insulin.

It has been known for some time, says Shooter, that NGF, like many other protein messengers, acts by attaching itself to a receptor on the membranes of responsive nerve cells.

Shooter and his associates, Drs. Sutter, Riopelle, and Harris-Warwick, recently discovered there are two different NGF receptors which vary in their location and binding strength. Only one of these is involved in the generation of nerve fibers, says Shooter.

So far, studies relating NGF to diseases such as tumors of the nervous system have been inconclusive, says Shooter. But the similarity to insulin, he says, suggests that abnormalities in NGF production, like insulin deficiency, may result in disease.

SCIENCE WRITERS: This story is released in conjunction with the presentation of a scientific report at the American Academy of Ophthalmology and Otolaryngology October 3 in Dallas, Texas.

ADVANCE FOR P.M. RELEASE MONDAY, OCT. 3, 1977.

STANFORD –

Tumors of the head and neck are now being treated with platinum chemotherapy by Stanford physicians.

Platinum, a heavy metal also used in treating cancer of the testes and ovary, caused tumor shrinkage in 75% of patients treated with advanced head and neck tumors, said Dr. Charlotte Jacobs, acting assistant professor of medicine.

Platinum is thought to act by attaching to DNA, the genetic material of cells, and preventing cell division.

Jacobs reported her findings Oct. 3 before the annual meeting of the American Academy of Ophthalmology and Otolaryngology in Dallas, Texas.

Head and neck tumors account for 5% of all cancers.

"They are one of the most deforming and debilitating of any cancer," said Jacobs.

Jacobs conducted the study with Dr. Willard Fee and Dr. Richard Goode, department of surgery; Dr. Don Goffinet, department of radiology, and Dr. Joseph Bertino, of the Yale University School of Medicine.

Sixteen patients were given 24-hour infusions of platinum, repeated every 3 weeks. The patients received 1-5 courses of treatment.

Ten of the patients had received prior surgery, radiation, or chemotherapy and had recurrent disease. The other six had received no prior treatment.

Some shrinkage of tumors occurred in 75% of the patients, said Jacobs. One patient had complete remission, and five had over 50% shrinkage of the tumors. The response rate was not influenced by location or size of the tumor, or by prior treatment, she said.

In comparison, methotrexate, another common cancer fighting drug, produces shrinkage in 30-50% of head and neck tumors. Most tumors treated with this drug recur after 2-4 months, said Jacobs.

However, Jacobs cautioned that only a longer period of time will determine if platinum is more effective than methotrexate in treating head and neck cancer.

Both drugs have side effects, including nausea and vomiting, and low blood counts. High doses of the drugs can damage the kidneys, she said.

Jacobs said she planned to continue testing platinum in patients with recurrent and advanced disease. It will be used in addition to surgery and radiation therapy in patients who have less than 50% chance of cure.

She also planned to test platinum with methotrexate to see if the combination is more effective than either drug alone.

FOR IMMEDIATE RELEASE
STANFORD –

Employee elections scheduled Feb. 2-4, 1978, at Stanford University Hospital may be canceled.

The reason is new legal issues that have emerged between United Stanford Employees (USE) and Stanford University.

According to Priscilla Wheeler, associate staff counsel at Stanford, the elections could be conducted only if USE officially requests that they proceed, or if the union withdraws its unfair labor practice charge in connection with a recent employee opinion survey at Stanford Medical Center.

The unfair labor practice charge alleges that the survey, which was conducted by the Hospital earlier this year, was designed to influence employee feelings on whether to select USE or other labor organizations as their collective bargaining agents.

Although the 20th region of the National Labor Relations Board (NLRB) in San Francisco found the USE charge without merit and refused to issue a complaint, the NLRB Office of Appeal in Washington, D.C., overruled the decision to dismiss and directed the San Francisco office to issue a complaint on the matter so that all issues could be heard.

The appeal to Washington had been filed by USE.

The matter will now be heard and resolved in a hearing before an administrative law judge.

Two years ago similar elections were held in the Hospital and Clinics. The balloting was conducted by the NLRB, and more than 1,000 of 1,200 eligible employees voted overwhelmingly to reject any union representation.

However, the results of those elections were set aside after an unfair labor practice complaint and election objections were filed with the NLRB by USE.

The USE complaint alleged that two minority employee groups—La Alianza Latina and the Black Advisory Committee—were unlawfully assisted and directed by the Hospital. Both employee groups have been active in affirmative action efforts.

USE, which is Local 680 of the Service Employees International Union, AFL-CIO, also claimed that Hospital assistance given the groups, including time off to attend meetings and the use of meeting rooms, was unlawful.

The NLRB rejected the USE claim that the groups had been "dominated" by the Hospital.

The setting of new elections resulted from the settlement of this dispute by Stanford and USE earlier this year.

However, as a result of USE's new charges, those provisions are no longer valid, says Paul B. Hofmann, director of Stanford Hospital and Clinics. The elections cannot be scheduled unless all outstanding legal matters are resolved, he said.

The employee opinion survey in question was held "when no union organizing campaign was under way and no election scheduled. The survey had been planned for a long time and without regard to any possible union elections," Hofmann added.

USE would be actively involved in any such elections. It represents about 1,350 technical maintenance and service employees at Stanford, including Stanford Linear Accelerator Center (SLAC). About 260 of approximately 5,000 employees at Stanford Medical School are USE members.

FOR IMMEDIATE RELEASE

STANFORD –

Stanford's original medical linear accelerator, the first to be used for treatment of cancer patients, will be on display beginning Dec. 1 in a major exhibit at the Smithsonian Institution's Museum of History and Technology in Washington.

"Atom Smashers: 50 Years," tracing the history of high energy particle accelerators, will be located on the Museum's main floor, and will remain open for several years.

After treating an estimated 8,000 patients during 16 years of use, the first medical accelerator was dismantled and donated to the Smithsonian in 1971 by Dr. Henry Kaplan, who had initiated its development.

The pioneering apparatus was used to destroy tumors by bombarding them with X-ray radiation produced from electrons. It was designed and built jointly by researchers in the Medical School's Radiology Department and the University's Microwave Laboratory, with grants from the American Cancer Society and the National Cancer Institute.

It was first installed in 1955 at Stanford's former teaching hospital in San Francisco, then moved to the Stanford campus with the Medical School in 1959.

Dr. Kaplan, then chairman of the Department of Radiology, first proposed the application of high energy X rays in the treatment of cancer. In the early 1950s existing megavoltage machines were far more expensive to install and operate than standard X-ray machines of the time, and were very cumbersome to use. The goal was to design one practical for cancer treatment, that could move and be aimed at different parts of the patient.

Edward L. Ginzton, then director of the Microwave Laboratory in the Physics Department, designed much of the machine and supervised its construction. He is now chairman of Varian Associates' Board of Directors, a Stanford University trustee, and a member of the Stanford Hospital board of directors.

Kaplan provided the medical specifications for design, and put it to its initial test.

For medical purposes, the electrons injected into a vacuum cylinder are accelerated by microwave power to a high velocity, then aimed at a specific tumor tissue, or used to produce penetrating X rays.

(more) 11/29/77 cr

One of Dr. Kaplan's first patients successfully treated with the apparatus was a two-year-old boy with retinoblastoma, a tumor of the retina in the eyes of young children that can lead to blindness.

The original model was particularly suited for treating cancers of the head and neck, prostate, or bladder, according to Kaplan. The young boy had lost the vision in one eye, but his other eye was saved when doctors were able to destroy the tumor with radiation from the accelerator.

Until that time most cancer radiotherapy used X-ray machines for essentially palliative treatment, to slow cancer growth and relieve pain temporarily, but was not able to destroy the cancer.

With the advent of megavoltage therapy, many malignancies once fatal began to experience higher cure rates. Today megavoltage accelerators are found in cancer centers around the world, and have contributed to high cure rates for cancers such as Hodgkin's disease, related lymphomas, and cancer of the prostate and bladder.

As Kaplan was thinking of ways to use megavoltage for medical treatment in the '50s, physicists on campus had already initiated development of the Stanford Linear Accelerator Center (SLAC). SLAC has also supplied the Smithsonian with a number of exhibits, and a significant portion of the "Atom Smashers" exhibit will trace 30 years of electron linac development at Stanford.

Individual units include high frequency cavity oscillators devised by William Hansen in the mid 1930s, illustrating the basic concept underlying microwave linear accelerators.

The Nobel Prize diploma awarded to Professor Burton Richter in 1976 will also be displayed, as well as his research log books of the epochal discovery of the unknown subatomic particles.

Superconductivity is represented by a section of the Stanford superconducting linac at the Hansen Laboratories on the Stanford campus.

Among the exhibit's objects are several historic accelerators, entire bubble chambers, spark chambers, and superconducting magnets used in experiments to study atoms and their interaction with other kinds of atomic particles.

FOR INFORMATION CONTACT: Spyros Andreopoulos, 497-6911
FOR IMMEDIATE RELEASE
STANFORD –

Stanford University School of Medicine has been advised by the Bureau of Health Manpower (BHM) that it will not receive federal educational support next year because it has failed to comply with the so-called Guadalajara clause of the 1976 health manpower law.

This provision requires medical schools to guarantee slots for Americans transferring from foreign medical schools. Students are to be admitted under standards set by HEW rather than each school's own academic criteria.

Stanford Medical School, in its application for funds earlier this year, told the BHM that it could not comply with this provision.

"We believe it is essential for the academic integrity and independence of universities that the critical judgments about standards for admission. . .be made by the university and not given over to an agency of the federal government," wrote Dr. Clayton Rich, dean of the School of Medicine.

The loss of funds to Stanford would be more than $400,000 next year.

Stanford was among 14 medical schools that received letters informing them that they would not be included in the capitation program as presently authorized.

According to the Association of American Medical Colleges (AAMC), they include University of California's five medical schools, Yale, Northwestern, University of Chicago, University of Illinois, Johns Hopkins University, Duke University, Case-Western Reserve, and Baylor College of Medicine.

The Bureau of Health Manpower, according to the AAMC, took steps to implement the present law, even though Congress is moving toward a major revision of the objectionable provision. If the provision is amended by Congress and becomes law, all schools, including the 14, could decide whether to reapply for the funds.

BHM sent telegrams to all medical schools last month asking for a final decision on the matter. Three schools, Harvard, St. Louis University, and Indiana University, which previously objected to the law, were mentioned in news reports as having decided to comply to receive the funds.

But Patricia Perry, special assistant to the dean of Harvard Medical School, told the Stanford Medical Center News Bureau that Harvard's position remained unchanged. "Harvard has reserved the right to challenge the constitutionality of the requirements in court, and to withdraw from further consideration in light of future changes. . .if they were not in the School's best interests," said Ms. Perry.

Dean David Chaloner of St. Louis University School of Medicine said his School applied for the funds because it has qualified for a waiver. The School faces physical limitations and cannot admit additional students.

"However," said Chaloner, "if the government insists on our adding more students to our entering class, then we will have to reject capitation."

Indiana University Medical School spokesman Joseph Lehman said the news reports were in error. "We will not accept any capitation if it means changing our admission standards," he said.

If Congress fails to amend the law, sources at the AAMC said deans of several schools are considering filing a suit, based on the First and Fourteenth Amendments of the Constitution, asking the courts to enjoin HEW from carrying out the law—that is, require the Department to award the funds to all schools which apply, and at the same time prohibit it from apportioning U.S. foreign medical graduates to any school.

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos 415: 497-6911

STANFORD--A new book about the application of statistical techniques to medicine and biology has been coauthored by Byron William Brown, Jr. of Stanford University, and Myles Hollander of Florida State University.

Statistics: A Biomedical Introduction, just published by John Wiley & Sons ($15.95), is based on lectures offered by Stanford and Florida State. The contents are designed for medical students, undergraduates in the natural sciences, and graduate students in biomedical fields.

Brown is professor and head of the Division of Biostatistics at the Stanford University School of Medicine. Hollander who received his Ph.D. in statistics from Stanford is professor of statistics at Florida State University.

The 456-page book covers topics taught in most beginning statistics courses, but the focus of the subject matter is an actual data analysis situations that arise in biomedical research.

Statistical techniques, according to the authors, allow the scientist to measure the strength of his conclusions, in terms of probability, and in a language that can be commonly understood by his peers around the world.

The book gives many examples on the application of statistical concepts to randomized clinical trials, medical surveys, clinical tests, and other procedures.

Editors: Review copies of the book available on request if not included with story.

STANFORD--A common-sense parents' guide to the medical problems of children--from birth through adolescence--has been coauthored by a Stanford University physician and two associates formerly from Stanford.

Taking Care of Your Child: A Parents' Guide to Medical Care (Addison-Wesley Publishing Co., 409 pp., $10.95 cloth) was coauthored by Drs. Robert H. Pantell, James F. Fries, and Donald M. Vickery.

A sequel to their successful Take Care of Yourself for adults, the new book is aimed at parents to help them make sound decisions when problems arise.

When to treat ailments at home and when to seek a physician's advice--a question that troubles parents--is a central theme of the book.

The authors describe a wide range of childhood injuries, allergies, problems and diseases--from cuts, burns, broken bones and poisoning, to croup, mumps, chicken pox and German measles.

Instructions for home treatment are provided. In addition, they discuss what kinds of diagnostic tests and treatment may be expected at the doctor's office, and the medical history the physician will require from the patient.

Decision charts, in large readable type, summarize the most pertinent questions and symptoms.

When a visit to a physician is recommended instead of home treatment, the charts indicate different levels of urgency--from "see physician now" to "make appointment with physician." Emergency signs which overrule the charts and dictate that medical help should be sought immediately are described.

In addition to guidance for the most common childhood medical problems, the authors discuss subjects that they have found to be of greatest concern to parents.

One section deals with self-care during pregnancy, infant feeding, home or hospital delivery, medications used during labor, delivery room procedures for newborns.

Care of the infant at home, physical growth and personality development are touched on. References are provided for further reading. Toilet training, eating habits, crying, temper tantrums and parent frustrations are discussed as well as day care centers, school problems and sexual development.

-more-

The authors provide a detailed explanation of immunizations: how effective they are; possible reactions and side effects; how long immunity lasts; whether boosters are necessary, and when they should be given. An immunization schedule is outlined.

Of special interest to parents is the book's discussion of upper respiratory infections.

Studies have revealed that the average child has between six and nine viral illnesses per year. In some children, these viral illnesses are so mild that the parent may not notice any symptoms except for a cough or runny nose.

"We do not think of these viral infections as illnesses," the authors state, "but rather as immunizations that serve to protect children against the more serious consequences of these illnesses at a later age."

The authors note, "There are at least 60 different viral strains against which most adults are partly immunized because of childhood illnesses. The sooner the child develops these immunities, the sooner the relatively illness-free years of the adult can begin."

They deplore the tendency of schools to send children home from school at the first sign of a cold since "the cold can serve to immunize the other children against that virus."

The authors' stress on self-reliance and conservative treatment is evident in their discussion of the "home pharmacy." "The vast majority of all medical problems resolve themselves without the use of any medication.... For nearly every advertised drug, there is a cheaper alternative that is just as good or better; in many instances, the preferred alternative is nothing at all."

In their discussion of commonly used drugs for colds, the authors point out both the beneficial and adverse effects of antihistamine compounds, oral decongestants, cough syrups, aspirin and others. Moreover, they stress that "only for bacterial infection does the doctor have more effective treatment than is available at home...viral infections and allergies do not improve with treatment by penicillin or other antibiotics.... Colds are almost invariably caused by viruses and do not...respond to antibiotic treatment." To distinguish between strep throats which should be treated with an antibiotic and viral sore throats, they advise that a throat culture should be obtained.

The most important medicine of all, the authors advise, is "tincture of time." Inappropriate reliance on drugs means that "although time will take the symptom away, the drug will take the credit. The child fails to learn that the body is strong, and thinks instead that health is frail and only precariously maintained by an intake of chemicals." The choice lies between "drug dependence or personal independence."

Pantell, an assistant professor of family practice and pediatrics at the Medical University of South Carolina, is a former Robert Wood Johnson Clinical Scholar at Stanford. Fries, also a Johnson Scholar, is an assistant professor of medicine at Stanford. Vickery who received residency training at Stanford is now president of the Center for Consumer Health Education, Inc. He is also affiliated with Georgetown Medical School.

FOR IMMEDIATE RELEASE

STANFORD –

Stanford University has filed suit against the state treasurer and controller, claiming the State of California owes it $448,800 in capitation support for increasing enrollment in medical school.

Originally filed with the California Supreme Court, the suit was transferred to the Third District Court of Appeal in Sacramento recently by the high court.

The University claims the state agreed to pay up to $12,000 for each student enrolled above a number fixed by the school's 1970-71 enrollment. The state contribution is determined after deducting the amount paid per student by the federal government. The state's contribution should have been $10,200 per student.

According to the suit, the reimbursement agreement was set up by the California legislature for the purpose of encouraging colleges and universities to increase enrollment in their medical schools.

Both the state and Stanford agree that the Medical School did increase its enrollment over the 1970-71 base year by 35 students in 1973 and 26 students in 1974. The University submitted its application for funds to the state for those increases and was paid, the suit says, but when a similar application was submitted for 44 students enrolled in 1975-76, it was not paid.

The state controller has refused to pay Stanford's latest bill in spite of legislation specifically approving such appropriations to private schools, according to the suit. The controller claims such payments may violate the state constitution.

The reimbursement provisions to medical schools were established, the suit said, because the state found existing medical schools could provide physicians and surgeons at a cost substantially lower than would be required to build new medical schools.

Stanford and the University of Southern California, the only two private institutions in the program, have both expanded their medical school enrollments beyond the levels called for in their contracts, according to the State Scholarship and Loan Commission, which administers the program.

The constitutional question about state subsidies to private schools was first raised in April 1975 by an attorney general's opinion concerning Loma Linda University. The opinion said the commission could not give money to Loma Linda because the school is run by the Seventh Day Adventist Church and is not publicly controlled.

The opinion cited a section of the California Constitution which covers all private institutions, not just those with church ties.

Article 9, Section 8 of the Constitution says, "No public money shall ever be appropriated for the support of any sectarian school or denominational school, or any school not under the exclusive control of the officers of the public schools."

The University argues that *bona fide* contracts serving important public purposes are not "support" under the terms of the California constitution.

STANFORD-- Two administrative appointments have been announced at Stanford University Hospital and Clinics.

Effective Dec. 11 David Mendelow will become associate administrator, while Kenneth G. Hill will serve as assistant administrator, beginning Jan. 9.

According to Peter J. Levin, associate vice president for medical affairs and executive director of Stanford Hospital and Clinics, Mendelow will be primarily responsible for the clinics and emergency services.

Hill, Levin said, will have responsibilities in the professional and patient care areas, including quality assurance programs, risk management, housestaff and medical staff.

Both Mendelow and Hill will report to Gary A. Mecklenburg, who will become administrator of the hospital and clinics on Dec. 16.

Levin also announced that John Kneepkens, who currently serves as associate director and who had previously indicated his intention to retire, will remain on the staff in an administrative capacity in the clinics.

Mendelow, 35, is currently a senior consultant for Arthur D. Little, Inc., of Cambridge, Mass.

In addition to consulting projects for several medical institutions in the U.S., he recently served as project director at the 1,000-bed University Hospital at the Federal University of Rio de Janeiro. He headed a team which designed the organizational and operational systems of the hospital.

Previously, Mendelow held various administrative positions at Albert Einstein College of Medicine in New York and the Bronx Municipal Hospital Center. He received his B.A. from Michigan State in 1963, and his M.B.A. in health care administration from George Washington University in 1967.

Hill is currently the assistant director of ambulatory services at Nassau County Medical Center in East Meadow, N.Y. He received his A.B. degree in political science from City University of New York in 1973, and his M.P.H. in hospital administration from Yale University in 1975.

Hill completed his administrative internship at St. Luke's Hospital Center and his residency at Kings County Hospital Center, both in New York City.

Hill, 29, has been responsible for programs, budget and planning of the ambulatory services of Nassau County Medical Center during his two-year term as assistant director. ### Mailed 11/21/77

FOR IMMEDIATE RELEASE

STANFORD –

Dr. John A. Luetscher, professor of medicine at Stanford University School of Medicine, recently received the 1977 CIBA Award for Hypertension Research for his role in the discovery of aldosterone, a hormone important in maintaining blood pressure.

Luetscher shares the $5,000 award with two other contributors to the discovery, Drs. James F. and Sylvia Tait of Britain.

The award is given each year by the American Heart Association's Council to recognize "important and meritorious research" toward better understanding and treatment of high blood pressure.

Aldosterone is a hormone secreted by the adrenal glands, which causes retention of sodium by the body. It is essential in maintaining the balance of body fluids and salts, says Luetscher, and must be replaced in order to ensure survival after the adrenal glands are removed or destroyed by disease.

Too much aldosterone can result in edema, or swelling of body tissues due to fluid retention, he says. It can also cause high blood pressure. People with high blood pressure have an increased risk of heart and kidney disease.

Luetscher and his associates noticed a relation between edema and salt retention in patients in the early 1950s. They later showed that the urine of these patients contained a material which behaved like an adrenal hormone and caused sodium retention in rats.

The material was crystallized and shown to be identical to the hormone isolated from the adrenal glands by the Taits.

Presently, Luetscher is exploring ways to regulate aldosterone, and developing methods to diagnose and treat patients with edema or high blood pressure and loss of body potassium.

FOR IMMEDIATE RELEASE

STANFORD –

Gary A. Mecklenburg has been appointed administrator of Stanford University Hospital and Clinics.

His appointment, effective Dec. 16, was announced Wednesday, Nov. 16, by Peter J. Levin, associate vice-president for medical affairs and executive director of the Hospital Cnd clinics.

Mecklenburg, 31, succeeds Paul B. Hofmann who has resigned to become the administrator and chief executive officer at Emory University Hospital in Atlanta, Ga.

Mecklenburg was appointed deputy director of Stanford University Hospital and Clinics in March 1977. Prior to that he was associated with the University of Wisconsin Hospitals in Madison from 1970 to 1977 as administrative assistant and later as associate superintendent.

He received his B.A. degree in anthropology from Northwestern University in 1968 and his M.B.A. degree in hospital administration from the University of Chicago in 1970. He served as an administrative extern at Presbyterian-St. Luke's Hospital in Chicago.

Mecklenburg received the Harold M. Coon, M.D. Award of Merit of the Wisconsin Hospital Association in 1974 recognizing him as Wisconsin's Young Administrator of the Year.

He and his wife Lynn have two children, ages 3 and 4, and live in Los Altos.

STANFORD –

The Big Game medical alumni meeting, sponsored by the School of Medicine and the Stanford Medical Alumni Association, is planned for Friday, Nov. 18.

Dr. W. Leroy Heinrichs, professor and chairman of the department of gynecology and obstetrics, will introduce the morning postgraduate course, "Disease Detection in the Early Fetus."

To be held in the Sherman Fairchild Auditorium, the course will feature Drs. Howard M. Cann, professor of pediatrics and genetics, W. Desmond McCallum, assistant professor of gynecology and obstetrics, and Paul A. Hensleigh, associate professor of gynecology and obstetrics.

A noon reception and luncheon for alumni, associates, faculty, and spouses will be held in the Palo Alto Holiday Inn. Featured speaker will be Charles L. Gould, executive director of the Hearst Foundations, on "Uncle Sam, the Medicine Man." Reservations are necessary for the luncheon.

A spouses' program in the morning will include an address by Dr. Gunther Nagel on his most recent book, *Jane Stanford: Her Life and Letters.* There will also be a tour of the Hanna-Honeycomb House on the Stanford campus.

FOR IMMEDIATE RELEASE
STANFORD –

The present NIH guidelines regulating recombinant DNA research are too restrictive and don't involve the public in questions of research policy in the right ways.

This was the consensus of a group of scientists meeting with Senator Edward Kennedy at Stanford University Medical Center Friday, Nov. 11.

Kennedy, chairman of the Senate Subcommittee on Health, visited Stanford as part of a fact-finding tour on various health and science policies.

"It's a charade," said Dr. Arthur Kornberg, Merner professor of biochemistry and Nobel prizewinner, referring to the guidelines. "You go through the guidelines knowing they are unnecessary, but the bureaucracy demands it."

Kornberg, who won his Nobel prize for synthesizing DNA, said tha the guidelines, established in the summer of 1976, were "unnecessarily strenuous."

"If you throttle the research here, it will be done somewhere else, and it will become a dark age here," he said.

Kennedy, who had sponsored legislation to regulate recombinant DNA research, said earlier he would withdraw the bill because of recent findings that suggest the research is not as dangerous as previously thought.

"We have had a great deal of experience with recombinant DNA research, and all the data point to the fact that there is no novel danger," said Dr. Stanley Cohen, professor of medicine and genetics.

Paul Ehrlich, professor of biology, said the dangers involved with the research are "trivial" when compared to other dangers "society is happily accepting all the time."

Cohen suggested that presently existing mechanisms regulating research in pathological organisms are adequate to govern recombinant DNA research.

"There is no rabies research act of 1978, or encephalitis act of 1979," he said. "Yet we don't see any epidemics of these organisms taking over the country."

Dr. Halsted Holman, Guggenheime professor of medicine, disagreed with the consensus of the group. He said he supported the legislation which Kennedy had proposed.

"The issue (of public involvement in research) has to do with the increasing power of science and technology over the health and well-being of individuals and clusters of individuals," he said.

"This is the first step on the route to being able to modify mammalian cells and do genetic engineering," he said.

Holman drew an analogy to informed consent in patient treatment. "If the physician has the technology that makes it necessary for the patient to be involved in the decision, because the physician can't know everything about the outcome, some form of societal analog is necessary for all technologies that can influence clusters of people."

Most members of the group confirmed the need for public input in research policy decisions, but they could not agree how to bring the public into the decision-making process.

Kennedy said people need to be involved at all stages of research, from "take-off" to "landing."

But some scientists felt that efforts to legislate research while it is evolving would stifle it.

"There is no way to predict what the next event in the laboratory or in a person's mind will be," said Dr. Joshua Lederberg, chairman of the Department of Genetics. "If you try to stifle the take-off, you'll have to stifle all research."

FOR IMMEDIATE RELEASE

STANFORD –

Sen. Edward M. Kennedy (D-Mass.) told a Stanford University audience Friday, Nov. 11, that Congress should guarantee stable and continuing support for biomedical and behavioral research instead of the changes in research priorities that have occurred in recent years.

"Upheavals are unfair to research scientists who have dedicated themselves in good faith to the directions mandated by Congress," Kennedy said.

"We must develop a greater capacity for the systematic allocation of health dollars among the health sciences."

Recently, Kennedy said, Congress enacted programs to combat heart disease, cancer, diabetes, and arthritis among others. In addition, commissions have been created to study federal programs in Huntington's disease, epilepsy, and multiple sclerosis.

"It is no wonder that Congress is now called the Disease-of-the-Month Club, "Kennedy said.

In establishing the national cancer program, he said, "it was never the intention of Congress to starve other areas of medical research to feed the cancer effort."

One of the priorities, the Senator said, is to correct the present funding imbalance at the National Institutes of Health, without curtailing the progress in the war on cancer.

Kennedy stressed, however, there are challenges in public policy which the research community must face as well.

"The public must be accepted as an active partner in the development and evaluation of biomedical research," he said.

The debate over recombinant DNA research is "the beginning of a new and more sophisticated interaction between science and society," he said.

"This is a constructive development that should be welcomed by the scientific community," Kennedy said. "We have an opportunity to broaden public understanding of science."

Kennedy said this concept of public participation in science policy has unsettled many members of the scientific community.

"They see it as a threat to the freedom of scientific inquiry," he said. "But the truth is just the opposite. The greatest threat to science is the lack of public understanding."

Kennedy was critical of the peer review system by which scientists sit on committees which dispense federal research funds.

(more)

He charged that broad areas of research have been ignored, giving nutrition, behavioral research, and research into the epidemiology of cancer as examples.

"The research community should be coming to us," he said. "You should be telling us there are important areas of medicine which are not now receiving the kind of support they deserve."

Kennedy also had some good news for Stanford officials. He said it is likely the new law which requires American medical schools to accept all U.S. students studying in foreign medical schools would be amended. Stanford has refused to accept this requirement as a matter of principle, thereby jeopardizing $410,000 in federal educational support for the Medical School.

The Senator called the provision an "unwarranted intrusion by the federal government into academic medicine."

But, he said, even if that particular provision is withdrawn, "federal prodding will continue and the constructive tension between the Congress and the nation's medical schools will continue."

Kennedy made clear that the taxpayer will support medical education and research if it is relevant to social needs. This includes continuing to subsidize medical education at an institution like Stanford only if the school turns out doctors who treat basic illnesses—not just researchers or sophisticated superspecialists.

Kennedy visited Stanford as part of a fact-finding tour seeking citizen input related to health and science policies. He is chairman of the Subcommittee on Health of the Senate.

Earlier in the afternoon he met with faculty, staff, and students, including scientists involved in recombinant DNA research and some who are critical of it.

The scientists were almost unanimous in assuring Kennedy that recombinant DNA research is basically safe. The Senator, who had sponsored a bill placing restrictions on such research, has now withdrawn the legislation, convinced that the research is not as dangerous as first believed.

"I consider the dangers to be quite trivial compared with other things that society lives with," commented biology Prof. Paul Ehrlich.

Dr. Halsted Holman, professor of medicine, told Kennedy that he supports the bill the Senator withdrew. He said that while he does not believe that recombinant DNA research is dangerous in itself, he warned it is part of the larger issue of the "increasing tolerance of science and technology, and it requires public debate."

At Stanford Kennedy also was briefed on the Stanford Health Project in Central California, a preventive effort to reduce the risk factors in heart disease.

Dr. John W. Farquhar, project director, told Kennedy that the federal investment in preventive medicine research should be expanded, with more funding for demonstration projects that stress health education.

Farquhar called for consideration of the formation of a federal institute of preventive medicine to carry out such programs.

FOR IMMEDIATE RELEASE

STANFORD –

The case filed by Dr. William Hayden against Stanford University Hospital has been sent back to the Board of Hospital Directors for a hearing.

Santa Clara County Superior Court Judge J. Barton Phelps ruled Monday, Nov. 7, that the hearing must occur within 75 to 90 days, implementing new hearing procedures adopted by the hospital board on Oct. 4, 1977.

In addition, the court instructed the hospital board to consider certain educational and patient care criteria in resolving the issues raised by the case.

According to University officials, Dr. Hayden, a community radiologist, applied for membership on the medical staff of the hospital and requested privileges in the division of diagnostic radiology.

The privileges involved use of facilities generally used only by staff radiologists.

While his original application was still pending before the hospital board, Hayden filed suit, contending that the hearing procedures established by the board would not afford him a fair hearing.

The hospital consistently argued during the court proceedings that the matter should be returned to the board for further hearings.

The hospital will begin immediately to arrange for Hayden's hearing, University officials said today.

CITY DESKS: If you plan to cover Senator Kennedy's speech, please contact the Medical Center News Bureau. Because of limited space in Fairchild Auditorium, we would like to know how many reporters will attend so that we can reserve seats.

FOR IMMEDIATE RELEASE

STANFORD –

Senator Edward M. Kennedy (D-Mass.) will speak at Stanford University Friday, Nov. 11.

Kennedy will discuss "Biomedical Research Policy" at 5:30 p.m. in the Sherman Fairchild Auditorium of the School of Medicine.

His visit, according to the Senator's office in Washington, is part of a fact-finding tour seeking citizen input related to health and science policies.

Kennedy is chairman of the Subcommittee on Health of the Senate. During his visit at Stanford Kennedy will hold meetings with faculty, staff, and students.

His talk is sponsored by the Robert Wood Johnson Foundation's Clinical Scholars Program at Stanford.

Clinical scholars are young physicians, skilled in clinical medicine, and pursuing added studies in nonbiological subjects. Among them are health care economics and organization, national health and science policy, and the relationship of science to the public.

Kennedy is the sponsor of a bill (S. 1217) which seeks to restrict the conduct of recombinant DNA research. At a speech recently in New York Kennedy said he had decided to withdraw the bill indefinitely and to replace it with a bill to extend the NIH guidelines for this research to the private sector for one year.

During this time a 50-member commission, privately sponsored, will examine the issue and report its recommendations for future legislation to the Congress.

Stanford Medical School officials expect considerable public interest in the Kennedy speech. Classroom M106 in the Medical School, equipped with closed-circuit television, will be used in the event of an overflow audience in Fairchild Auditorium.

FOR IMMEDIATE RELEASE

STANFORD –

Some blind people appear to live as if they were in an underground bunker, says a researcher at Stanford University Medical Center.

Dr. Laughton Miles, physician specialist at the Sleep Disorders Clinic and chief of chronobiological research at the Institute for Medical Research in Santa Clara, and his associates found that a blind man with a severe cyclic sleep-wake disorder had circadian biological rhythms which were longer than 24 hours and indistinguishable from the period of the lunar day (24.8 hours).

The study was reported in the October 28 issue of *Science* magazine.

Most people are geared to live 24-hour days, even though their natural biological rhythms are closer to 25 hours, says Dr. Miles.

"If you put them in an underground bunker and isolate them totally from time and social cues, most people will begin to follow a circadian rhythm of about 25 hours," he says.

"In this sense, our patient does not have an abnormal rhythm. It's as if he were in an underground bunker."

The patient, who was totally blind from birth, had difficulty gearing himself to a 24-hour time frame. At regular intervals he suffered from insomnia and excessive day-time sleepiness.

When he did not force himself to go to sleep and awaken the same times each day, he spontaneously adopted a sleep-wake cycle of 24.9 hours. Cyclic rhythms of the patient's body temperature, alertness, and performance on psychological tests also had 24.9-hour periods.

The researchers found that some of his body functions exhibited the same rhythmic pace. The serum level of cortisol, and levels of certain minerals excreted in the urine, rose and fell in cycles that were 24.9 hours long.

"Almost any bodily function undergoes rhythmic changes," says Dr. Miles, "and almost certainly will have a circadian rhythm with a rise and fall during each 24-hour period."

Biological rhythms may be determined by so-called biological clocks, primitive time-keepers which are thought to exist in every organism, says Dr. Miles. They may also be influenced by the environment, the rising and setting of the sun, the moon, and the earth's electromagnetic field, he says.

The researchers observed that the onset of sleep in their patient coincided with the local low tide at the time of the experiment.

The patient continues to have problems imposing a 24-hour day on his 24.9 hour natural clock, despite several forms of therapy, including hypnotic and stimulant drugs, says Dr. Miles.

Dr. Miles and his associates surveyed 50 people with varying degrees of blindness and found that 38 of them complained of some type of sleep-wake disorder. Forty percent of the disorders were described as cyclic or epidosic.

Dr. Miles cautions that the survey involved a selected group and was not necessarily representative of the total blind population. The incidence of cyclic sleep-wake disorders among the general population is totally unknown, he say.

"It is natural to assume that the disorder is somehow related to our patient's lack of vision," he says. "However, studies have shown that not all totally blind people have this disorder. Under certain circumstances it may also occur among sighted people."

FOR IMMEDIATE RELEASE

STANFORD –

Dr. Stanley N. Cohen, professor of medicine and genetics at Stanford University School of Medicine, and Dr. Herbert W. Boyer, of the University of California, San Francisco, have jointly received the 1977 V.D. Mattia Lectureship Award for developing techniques for recombining DNA, the genetic material present in every organism.

The $5,000 award recognized "the discovery of an immensely powerful approach to the basic and applied molecular genetics of higher organisms—based on the development of procedures for transferring the genetic information of any organism into the DNA of another living organism."

In 1973 a team of scientists lead by Boyer and Cohen reported the first procedure for constructing biologically active recombinant DNA molecules outside of living cells.

The next year they reported the first successful propagation of animal genes in bacteria. The animal genes are carried into the bacteria by plasmids, where they become part of the bacteria's genetic make-up in subsequent generations.

Plasmids are circular bits of DNA in bacterial cells which can reproduce independently of cellular reproduction.

The researchers introduce new genes into the plasmids by using an enzyme to cut the DNA into fragments with sticky ends. Gene fragments from different organisms can then be "stuck" together, or recombined.

This technique has become a useful tool in the study of basic genetics and the mechanisms of genetic control. It may also enable researchers to construct new strains of bacteria useful in medicine and agriculture.

Specific genes may be introduced into common bacteria for the synthesis of insulin or antibodies, or to cure certain hereditary diseases. Recombination in plant cells may produce new, more desirable plant types.

The V.C. Mattia Lectureship was established in memory of the late Dr. Mattia, former president of Hofmann-LaRoche Inc. It is administered by the Roche Institute of Molecular Biology in New Jersey.

Among previous recipients is Dr. Paul Berg, Willson professor of biochemistry, who was recognized for "fundamental discoveries in protein synthesis" in 1972.

Skin cancers are being treated by heat in clinical trials conducted by Stanford University Medical Center researchers

"We think our results are encouraging," says Dr Jane Marmor, assistant clinical professor of medicine. "Heat certainly isn't a cure for cancer, but it may increase the effectiveness of other forms of treatment."

Marmor is conducting the trials with Dr. George M. Hahn, associate professor of radiology. Her remarks were based on a presentation given at the annual meeting of the American Society of Therapeutic Radiologists in Denver, November 3

Since the study began in March, 1977, 17 patients with recurrent cancers on the surface of their skin who had heavy radiation therapy in the past have been treated with heat produced by an ultrasound device.

The tumors, which are no larger than four centimeters in diameter, are heated to 42-44 degrees Centigrade (106-110 degrees Fahrenheit) with a special ultrasound device. Some shrinkage of tumors occurred in 50% of the patients after six 30 minute treatments, says Marmor.

Thirteen patients with surface cancer which had spread from elsewhere in the body were treated with heat and radiation The tumors were heated to 42-44 degrees Centigrade before and after irradiation. About 50% of the tumors regressed more than those which received radiation alone, she says.

The majority of patients with squamous cell carcinoma of the head and neck showed a favorable response to heat, says Marmor "This cancer is probably more sensitive to heat," she says.

Marmor says Hahn has found that hypoxic tumor cells, which are resistant to radiation, are more sensitive to heat than cells with an adequate oxygen supply The combination of heat and irradiation, she says, may be effective in killing both types of cancer cells.

The big problem will be developing methods of treating deep seated and large tumors safely and effectively, says Marmor Present methods limit treatment to surface tumors with a maximum diameter of four centimeters, she says

Another problem is that tumors do not have a uniform blood supply. The smaller the blood supply, the greater amount of heat delivered to cells in a region of the tumor. This means that temperature may vary over the whole tumor, says Marmor

The clinical trials began this year after the relative success obtained in animal trials. So far, 22 dogs and cats with spontaneous surface tumors have been treated with heat Approximately 50% of them had a positive response, she says

Again, animals with squamous cell carcinomas responded better than those with other kinds of skin cancers

Hahn and Marmor are now testing the potentiating effect of heat of chemotherapy in mice. Three common anticancer drugs, bleomycin, adriamycin, and nitrosourea, increase killing of cancer cells in tissue culture when heat is applied, says Marmor

The clinical trials and animal studies are part of a nationwide study, and are supported primarily by the National Cancer Institute

Correcting cosmetic defects, growing new skin for grafts in burn patients, repairing breaks in nerves-these are some of the applications of the purified collagen developed and now being produced by Stanford researchers.

"Collagen is the fundamental structural protein of the body in all higher organisms," says Dr. John R. Daniels, assistant professor of medicine. "It makes up 60% of all body protein and 98% of the cortex of bone."

Daniels and his associates have developed a technique for liquefying collagen from animals and stripping away the antigens, or protein markers, which elicit rejection when placed in other organisms.

The liquid collagen is injected under the skin to correct tissue contour defects such as severe acne scarring.

"The body accepts this material as itself," says Dr. Terry R. Knapp, one of the codevelopers. "Within two weeks it repopulates the implant with its own cells and feeds it with its own blood supply." The implant becomes living tissue indistinguishable from the skin around it, he says.

Knapp is a plastic surgeon practicing in Eureka, California, and also a member of the Stanford clinical faculty

So far 101 patients have been treated for tissue contour defects with injections of the purified collagen. In most cases, says Knapp, implantation has resulted in lasting and substantial correction of the defects.

This technique has been patented by Stanford University, and another patent is being sought for the purification process

In 1975 Daniels and Knapp joined with Ed Luck and Dr. Rod Perkins, who were also experimenting with purified collagen, and formed a corporation to finance the development of a whole family of collagen structures.

Luck, on leave from the University of Washington Medical School, and Perkins, a Palo Alto physician who specializes in diseases of the middle and inner ear, were working on the development of collagen structures which could be implanted in the ear One of these, an implantable ear drum, is now in clinical use.

The Collagen Corporation presently is purifying collagen on a large scale to be used in a widespread clinical trial of its effectiveness as an implant

Dermatologists and plastic surgeons in Palo Alto, San Francisco, Los Angeles, Ann Arbor, Michigan; Madison, Wisconsin; Syracuse, New York; and New York City will be involved in testing the implant, says Knapp.

Knapp and Dr Russel Pardoe, head of the burn unit at Santa Clara Valley Medical Center (SCVMC) and assistant professor of surgery at Stanford, also have used purified collagen as a dressing for burns.

Burns are dressed usually with grafts taken from the patient or with pig's skin. These dressings are rejected by the body because of foreign proteins they contain, and must be replaced every 2-4 days unitl a permanent skin graft is done, says Luck

The collagen membrane needs to be replaced only once prior to grafting because it is highly purified of all contaminants Limited clinical trials have shown it to be as effective as the patient's skin and more effective than pig's skin in preventing water loss and providing a protective barrier, says Knapp.

The dressing has been tested at SCVMC, St Francis Hospital in San Francisco, and Parkland Hospital in Dallas, Texas Further work is planned to develop a burn covering which could be retained permanently, and would become part of the patient's own skin, says Knapp

Dr. Ernest Kaplan, associate professor of surgery, has been participating in the clinical trials of the implanted collagen, and also is using collagen membrane as a template on which to grow new skin.

(more)

collagen in solution 2- 2- 2

Small pieces of the outer layer of skin, the epidermis, are placed on collagen membrane in a tissue culture medium. Because the collagen is similar to dermis, the deeper layer of skin, the epidermis patch grows onto it and forms a larger sheet of new skin.

Transplantation into the animals from which the epidermis patch was taken has been done without rejection, says Kaplan, and clinical trials are planned for patients.

New skin grown in this way could be used instead of grafts in patients with burns over large parts of their bodies, he says.

Joseph Rosen, fourth-year medical student at Stanford, and Kaplan are using collagen membranes to repair severed nerves in the legs of rats.

Nerves are surrounded by a membrane which contains collagen and which gives them structural support. Severed nerves are usually repaired by placing sutures through this membrane.

Rosen and Kaplan wrap a square piece of purified collagen membrane around the break in the nerve instead. The membrane sticks to the nerve like a piece of tape.

The extent of regrowth in nerve fibers after repair is measured by counting the number of fibers which fire, or display an electrical signal, when stimulated at various points on either side of the break, says Rosen.

In a normal, uninjured nerve, 100% of the nerve fibers within it fire when stimulated. If the nerve has been cut and sutured back together, only 50-60% of the fibers regain their capacity to fire. But if the severed nerve is wrapped with collagen membrane, nearly 90% of the function returns, says Kaplan.

The collagen membrane may aid nerve regrowth by preventing branching of nerve fibers, the in-growth of scar tissue, or by acting as a protective membrane, says Kaplan.

In addition, he says, "all sutures are foreign bodies that cause inflammation and scarring, both of which decrease nerve viability. The sutureless method prevents destruction of tissue due to inflammation."

Clinical applications of this work may be in improving the regrowth and therefore functionality of nerves which have been severed, says Rosen. Now, for example, suture of the severed medial or radial nerves in the wrist results in only partial recovery of use in the hand.

Kaplan and Rosen recently were awarded a two-year grant from the National Institutes of Health to continue their study.

Since every tissue in the body is either made out of or supported by a collagen structure, there are other applications for purified collagen. Perhaps one day heart valves, tendons, membrane surrounding the brain, parts of the eye, cartilage, and even bone will be made from purified collagen, says Knapp.

The bionic man is theoretically possible, he says.

STANFORD –

Paul Hofmann, director of the Stanford University Hospital and Clinics, plans to leave his post to become administrator and chief executive officer of Emory University Hospital in Atlanta, Georgia.

Hofmann, 36, also will be an associate professor in the department of preventive medicine and community health at Emory medical school

The appointments are effective January 1, 1978.

In a letter to Peter J. Levin, associate vice-president for medical affairs, Hofmann said he was leaving Stanford "with considerable ambivalence . . . My five-and-a-half year association has been a very challenging and rewarding experience."

During Hofmann's tenure Stanford completed planning and construction of a new hospital wing and hemodialysis center. It developed plans for major renovation of the nursery to provide needed space for the comprehensive neonatal services of the unit. It initiated a chaplaincy program, and a Northern California-wide training program for paramedics.

Hofmann also was responsible for starting a management systems engineering program credited for improving productivity and reducing costs

In 1976 Hofmann was presented the Robert S. Hudgens Memorial Award of the American College of Hospital Administrators "as the outstanding young hospital administrator of the year."

Hofmann received his bachelor of science and master of public health degrees from the University of California at Berkeley

He joined Stanford as deputy director in 1972, becoming director of the Hospital and Clinics in 1974. Prior to his appointment he was the associate administrator of San Antonio Community Hospital in Upland and a faculty member in hospital administration at UCLA

At Stanford Hofmann also taught in the department of family, community, and preventive medicine

As an administrator Hofmann has been concerned with the legal and ethical dilemmas of modern hospital care. He was a strong advocate and supporter of the Natural Death Act enacted by California in 1976

He also has been active in state and national hospital organizations, including the chairmanship of the American Hospital Association's council on research and development

STANFORD--Peter J. Levin, formerly an associate commissioner in the Department of Health, New York City, is the new executive director of the Stanford University Hospital and Clinics.

The appointment was announced recently by Dr. Clayton Rich, vice-president for medical affairs and dean of the School of Medicine.

Levin came to Stanford in 1977 as an associate vice-president for medical affairs, a position he will hold in addition to his new duties.

Levin is a 38-year-old Harvard graduate, with a masters degree in public health from Yale University, and a doctorate in hospital administration from the Johns Hopkins School of Hygiene and Public Health.

Before becoming associate health commissioner in New York, he served as executive director of New Haven Health Care, Inc., and acting executive director of the Bronx Municipal Hospital Center, New York.

He also taught at Albert Einstein College of Medicine, New York University and Yale.

FOR IMMEDIATE RELEASE

STANFORD –

Dr. Roger D. Kornberg has been appointed professor of structural biology in the Stanford University School of Medicine.

His appointment, announced Monday, Dec. 19, by Dr. Clayton Rich, vice-president for medical affairs and dean of the Medical School, will be effective Jan. 1.

Kornberg, 30, is currently assistant professor of biological chemistry at Harvard Medical School.

His father, Dr. Arthur Kornberg, is Merner professor of biochemistry and winner of a Nobel prize for DNA research in 1959.

Dr. Roger Kornberg is studying the expression of genetic information contained in the long, helical molecules of DNA. DNA exists in the cells of organisms as a complex with proteins. The complex, called chromatin, permits packaging of DNA molecules into a small area, and prevents them from becoming entangled when they are reproduced.

In 1974 Kornberg proposed a three-dimensional model of chromatin structure which has now become widely accepted, according to Dr. Lubert Stryer, chairman of the structural biology department.

His studies may help scientists understand how the chromatin structure and the proteins which bind the DNA affect the expression of genes.

A native of St. Louis, Mo., Kornberg received his B.S. in chemistry from Harvard (1967) and his Ph.D. in chemistry from Stanford (1971). He did postdoctoral work at the MRC Laboratory of Molecular Biology in Cambridge, England, before coming back to Harvard. In 1973 he was a junior fellow of the Society of Fellows of Harvard University.

Kornberg has authored numerous papers, and is a member of the editorial board of the *Journal of Cell Biology.*

His long-range research interest is cell ultrastructure and morphogenesis, the growth and formation of cells.

FOR IMMEDIATE RELEASE

STANFORD –

Children will be allowed to visit their newborn brothers and sisters in the maternity unit at Stanford University Hospital beginning Christmas Eve, Dec. 24.

Under the supervision of a responsible adult, siblings of the newborn may visit with both mother and baby during regular visiting hours, 6:30 to 8 p.m. daily.

Previously, children under 16 years could only visit outside the maternity unit in the solarium.

The new policy allows children to view the newborn through the nursery window, and also to visit with the mother and newborn in the mother's room.

The Hospital Medical Board recently approved a three-month trial period for the practice. According to Dr. William Aronson of Palo Alto, chairman of the Hospital's Perinatal Care Committee, the visitation policy may become established practice after the initial evaluations.

The Birth Action Council, a group of parents in the community who have given birth at Stanford during the past year, consulted with the Hospital committee to draw up the new policy.

Suzanne Arms of that group noted that the parents worked as a resource group, and see the new policy as "a very positive move to meet the normal, spontaneous needs of healthy mothers and babies."

The new rules call for a responsible adult to accompany and supervise the child at all times. Parents will be responsible for the safety of the newborn while siblings are present.

Rules also call for children to wash their hands before touching the infant.

According to Dr. Aronson, "it is essential that parents make sure that children with infections, such as colds, coughs, or those who have been exposed to communicable diseases, do not visit the mother or baby."

Dr. W. Leroy Heinrich, chairman of the Department of Gynecology and Obstetrics, notes that "family bonding around the newborn is one of the most important considerations in the new practice. . .sibling visits confirm that parent-child relationship at a time when the newborn may create anxiety for the other children in the family."

Dr. Heinrichs says the policy is consistent with the increased interest new parents are expressing in relating pregnancy, birth, and parenthood in terms of the whole family.

In addition to children's visits, the Medical Board also has approved rules that will allow fathers to assist at Caesarean deliveries.

Ms. Arms, author of "A Season to be Born," and "Immaculate Deception," calls the new policy "a recognition of that fact that all births are primarily family events." Sibling visits, she says, "are an answer to problems raised by leaving the other children at home who may feel abandoned."

STANFORD –

New state guidelines for teaching doctors about human sexuality are being opposed by officials at Stanford University School of Medicine.

The concerns focus on whether a state agency should draw up detailed guidelines for teaching human sexuality in medical schools.

While agreeing that physicians should have adequate instruction in the subject, Dr. Clayton Rich, dean of the Medical School and vice-president for medical affairs, objects to the specific teaching standards proposed by the Board of Medical Quality Assurance of the Division of Licensing.

"These proposed standards constitute a fundamental departure from the principle of academic self-determination which traditionally has afforded universities the right to establish academic policy free from governmental intervention," says Dr. Rich.

Such detailed standards are not listed for other required subjects, like pediatrics or surgery.

The legislation, AB 4179, was introduced by Assemblyman John Vasconcellos and signed into law in 1976.

All medical schools in California already teach the subject, and there is general agreement about the importance of such a course. But there has been widespread concern over the way the legislation is being implemented.

Several other medical schools, including the University of Southern California, Loma Linda, UC-Los Angeles, UC-San Diego, UC-San Francisco, and UC-Davis, have written to the Division of Licensing expressing objections to the proposed guidelines, but concurring with the intent of the law.

These guidelines require at least one identifiable and separate course on human sexuality, taught by a multidisciplinary faculty. The course must be at least 30 hours long, cover a list of specific topics, and include explicit sexual material. At the end of the course the student should be able to take a sexual history and develop a patient management plan.

The Stanford curriculum meets almost all these standards, and has pioneered in developing teaching in the field, says Dr. Michael Jacobs, assistant professor of medicine. He is instructor of the course, "Sexual Matters in Medical Practice." Nevertheless he objects to a state regulatory agency proposing standards in such detail, traditionally a matter left to the faculty of the school.

(more)

"As a teacher of a relatively new subject, I object to an agency telling me how to teach, especially when the standards are based only on what has been done previously in the field," says Jacobs.

"It's like taking a redwood sapling and making it a bonsai," he comments. "The requirements would constrain future development of the course, for example, by precluding development of a single competent faculty."

At the present time Stanford is examining the possibility of legislative relief from the requirements, possibly by substitute amendments. In letters to several legislators, Dr. Rich has supported the inclusion of human sexuality in the curriculum, but he has objected to having a regulatory agency set forth in such detail any part of that curriculum.

He notes that "if the state is prepared to regulate the details of the curriculum in one area, it can and may do so in others. This would establish a precedent and possibly a trend that seriously threatens the quality of all the public and private universities in this state."

A less drastic course, says Rich, may achieve the objectives intended by the law, and make extensive state requirements unnecessary.

In addition to the specific course on sexuality, Stanford offers a variety of instruction in the subject, including segments of courses in physiology, anatomy, embryology, physical diagnosis, and others. Portions of many clinical clerkships cover topics like counseling and therapy for sexual dysfunctions, pharmacologic causes, and physical disability.

Jacobs' course is offered every other year to first- and second-year medical students by the Division of General Internal Medicine. A popular course, it has received high ratings in evaluation questionnaires, and attracts more than 100 students, plus their spouses or guests.

Guest speakers include psychiatrists and sex therapists, pediatricians, nurses, social workers, and others. Representatives of alternative sexual life-styles are invited to speak, including prostitutes, homoxesuals, lesbians, sadomasochists, and transsexuals.

Jacobs notes that earlier this year medical schools formed a consortium to pool resources for reviewing the teaching of the subject. That task force, he says, has been a positive outgrowth of the early concerns about adequate instruction.

He notes that a high percentage of the state's physicians receive their training in medical schools in other states, and then come to California. Specific curricular requirements, he says, might compromise the ability of non-California graduates to be licensed in the state.

STANFORD--Five university presidents Thursday, Dec. 8, in a joint statement praised Congress for acting "decisively to restore our autonomy in the university admissions process."

The statement was issued after the House of Representatives yesterday gave final passage to a bill repealing the so-called Guadalajara clause of the 1976 health manpower law.

The bill was approved unanimously and sent to the President for his expected signature.

"We regard this explicit recognition of the principle of academic freedom in university admissions as a reaffirmation of the basic values that have made American universities strong and independent," the statement said.

Previously the law required medical schools to guarantee slots for Americans transferring from foreign medical schools. The students were to be admitted under an allocation formula set up by the secretary of the Department of Health, Education and Welfare without consideration of their academic qualifications.

Medical schools were to admit such students as a condition of receiving capitation or federal educational support.

Under the new law, medical schools are now asked to give assurances that they will seek to increase their third-year enrollment by five percent, but the increase need not come solely from foreign transfer students or from any other particular source.

The schools are free to apply their own admission criteria in evaluating applicants to achieve increased enrollment.

In addition, the new law contains a provision inserted at the request of Stanford and other California medical schools by Sen. S.I. Hayakawa, which insures that students will be eligible for federally insured loans regardless of their school's eligibility for capitation support.

The university presidents who issued the statement are Terry Sanford, Duke; Derek Bok, Harvard; Steven Muller, Johns Hopkins; Hanna Gray, Yale; and Richard W. Lyman, Stanford.

It said in part: "We are pleased that Congress has acted to repeal the provisions of the Public Health Service Act that would have made receipt of capitation funding dependent upon the schools' willingness to admit an unknown number of students...without regard to their academic qualifications....

"For the past year we have voiced our strong objection to these provisions as a violation of a university's basic academic freedom: the right to apply its own admission criteria, including academic requirements in selecting its students.

"Despite the financial costs of being declared ineligible for capitation support, we then notified appropriate members of Congress that, while we were prepared to take steps to increase our enrollments of qualified transfer students, we could not abdicate our responsibility to determine those qualifications.

"Congress has now responded positively to those objections.... The schools are free to apply their own admissions criteria in evaluating applicants and in attempting to achieve the increased enrollment."

Last month 14 schools, including Stanford, were notified by the Bureau of Health Manpower that they would not be included in the capitation program as previously authorized. The loss of funds to Stanford would have been more than $400,000 next year, and more than $11 million for the 14 schools.

Under the new law it is expected that Stanford as well as other medical schools will reapply for funds.

STANFORD--Dr. Thomas J. Fogarty, Palo Alto heart surgeon, has been elected president of the medical staff at Stanford University Hospital.

Dr. Fogarty was elected to a two-year term by mail ballot of the active medical staff, according to Dr. Lawrence Crowley, chief of staff. The new post of president was adopted in accordance with new bylaws of the medical staff.

The president will serve as the representative of the medical staff to the Medical Board, to the chief executive officer and the Hospital Board of Directors. He will preside at medical staff meetings, serve as a member of the Medical Board, and participate in the joint conference committee, a forum for discussion of Hospital policies and practices.

Dr. Fogarty has been in the private practice of cardiovascular surgery since 1973.

He received his M.D. degree from the University of Cincinnati College of Medicine in 1960, and served internship and residency at the University of Oregon Medical School. After a post as clinical associate at the National Heart Institute in Besthesda, Md., he was a research fellow, chief resident and instructor in surgery at Stanford.

He has served as assistant professor of surgery, and assistant clinical professor of surgery at Stanford.

STANFORD--There is an unusual school at Stanford Hospital.

Sponsored by the Palo Alto Unified School District (PAUSD), the school meets the educational needs of hospitalized children.

Pupils in the program range from kindergarten through sixth grade, with an occasional junior or senior high school student.

Length of stay in the program varies from several days to several months, but the average is about one week, according to Rosemary Clark who has been the teacher at the Stanford hospital school for more than four years. An average of 10 children are in the program at any one time.

Mrs. Clark tries to meet each child's individual needs by maintaining contact with the child's regular teachers. Conferences with attending nurses keep her informed about the physical condition of the child. If the child cannot come to the classroom, she goes to the student's bedside.

To motivate hospitalized children is a challenge, notes Mrs. Clark. She uses a wide variety of educational tools such as games, painting and drawing, music, filmstrips, tape cassettes, puzzles and cards.

The hospital teacher, who must have a special credential to teach orthopedically handicapped or health-impaired children, is hired by PAUSD. Secondary school teachers may be called upon to tutor children in math, sciences, and other specialized subjects.

The hospital school at Stanford was started in 1968 by Dr. Catherine Leland, chief resident in pediatrics. By providing children with an actual school room where they could go for their lessons--even if they had to be wheeled in on a gurney,--Leland hoped to lessen the trauma of hospitalization and create a link between the hospital and the outside world.

PAUSD offers a similar program at Children's Hospital at Stanford, an independent center affiliated with the medical school. Three full-time teachers work with patients being treated for chronic illness. Because of the nature of their disabilities, these children may be hospitalized several times a year. Additional teachers are called upon, when needed.

Attendance at the hospital schools is not required, but most children want to come, says Katherine Croke, former coordinator of the PAUSD department of education for physically handicapped children.

"Children fear being left behind--that their classmates will be going on without them," said Mrs. Croke. "Knowing that they are keeping up with their class provides a tremendous

-more-

psychological comfort for the children.

"The very act of going to school enables a child to keep a healthy, active and optimistic image of himself."

The pediatrics department at Stanford hospital also includes a recreation therapy program especially designed to alleviate the trauma that can occur through hospitalization and illness.

"Play is a vital part of a child's life. The sooner children return to normal activities, the sooner they get well," says Betty Lovelace, pediatrics recreation director. "By recognizing the needs of the healthy part of each child, the school and recreation staffs work closely together to provide psychosocial support for each patient."

Children are encouraged to go to the playroom--whether by walking, in wheelchairs, or on their beds--so that they can participate in activities normal for their age group and interact with other children.

Special activities may be devised to meet the child's needs. If leg muscles need strengthening, the child takes part in kick-target games. If a youngster is in traction and unable to move, substitute mobility is designed. A basketball hoop may be attached to the end of his bed and the ball tied to a string to provide independent retrieval. Children who require a special diet learn to prepare foods and plan party refreshments. All activities are designed to increase the child's self-confidence and independence, even in the face of a new disability, notes Lovelace.

Prior to admission, children are encouraged to attend a special show, "A Visit to the Hospital". Opportunities are provided to explore other parts of the hospital and to handle equipment.

After children enter the hospital, a miniature toy hospital, complete with doctors, nurses, and an operating room, helps prepare them for surgery.

"Anxiety is a normal reaction to stress. We find that children who are well-prepared are better able to cope with each aspect of the hospital experience," says Lovelace.

To alert staff to the children's needs, young patients are asked by the teacher to write or dictate a story about themselves. These are a few examples:

"There is a tube coming from my heart which is constricted. I am scared that I am going to have a lot of pain."

"Having shots is the worst thing about being in the hospital."

"The hospital is scary because you don't know what is going to happen."

"I wish I could stay awake so I could see what is inside of me."

"I came ...to have my heart fixed. Sometimes I get tired when I run. Sometimes I get tired when I jump rope. When I walk to school I get very tired."

"It's nicer to be home than any other place, especially the hospital."

STANFORD--Patient occupancy at Stanford University Hospital during the last three months is 10 percent lower than the level anticipated in the budget, according to Paul Hofmann, hospital director.

Lower occupancy means more people are either staying out of the hospital or getting out more quickly, but it creates problems for administrators who must also be concerned with the economic well-being of the hospital.

"On the one hand, we are pleased with the general indicators that suggest that people are healthier and in less need of hospitalization," says Hofmann. "On the other hand, we must be concerned economically as a major employer."

Beds used for patient care by members of the Medical School faculty are 84.2 percent occupied. However, only 58.1 percent of the beds reserved for patients of community physicians presently are in use.

As a result, the hospital is taking steps to reduce the economic impact of decreased patient occupancy. A 32-bed unit in Hoover Pavilion was closed October 21, and the staff assigned to other units.

Hoover Pavilion is located across Quarry Road from the Stanford Shopping Center. It supplies 177 of the 643 beds in the hospital. Patients under the care of community physicians use 150 of the Hoover Pavilion beds.

According to Hofmann, another unit in Hoover Pavilion will be closed in anticipation of the decrease in admissions which usually occur during the holiday season.

In addition, staff are being encouraged to take vacation time and absent time. New and vacant personnel positions are being left unfilled unless needed by increased workload.

The drop in occupancy, however, has not relieved the demand for use of operating rooms, says Hofmann. There are 14 operating rooms in the main hospital and two at Hoover Pavilion available to faculty and community physicians.

The problem stems from an increase in patients receiving surgery who require more acute care, he says.

Other hospitals in the Bay Area, including Marin General Hospital in Marin County and University of California, San Francisco, Medical Center, have also experienced a decline in occupancy over the past three months.

-more-

Seven percent fewer beds were occupied at Peninsula Hospital in Burlingame during this period than were expected from last year's figures, according to hospital administrator Charles Mason.

"Doctors at the Menlo Medical Clinic in Menlo Park have told me they're not hospitalizing as many patients as they have in the past," says Henry Burget, clinic administrator. Most of the physicians at the clinic hospitalize their patients at Stanford.

Community physicians who are members of the medical staff at Stanford hospital can use up to 370 beds for care of their patients, according to the 1968 contract by which Stanford University bought Palo Alto's share of the hospital. Priority of admissions to these beds is given to patients who live in Palo Alto.

The difference between occupancy of beds reserved for community physicians and those used by the faculty reflects differences in the conditions of their patients and length of stay in the hospital, says Hofmann.

Many faculty members treat specialized, acute disorders in patients referred by other physicians, he says. These patients tend to require more complex diagnostic and therapeutic procedures, and usually stay longer in the hospital than patients treated by community physicians.

Hofmann cites several reasons for the decrease. With the advent of self-care, more people are taking care of themselves, rather than going to physicians.

Improvements in medical care, particularly in the use of antibiotics, also have reduced the need for hospitalization for a variety of conditions, such as pneumonia.

Once admitted to the hospital, patients stay for shorter lengths of time. The average length of stay at Stanford is one week. This may reflect actions of the concurrent review committee of the hospital, a group of physicians on the medical staff who evaluate admissions and length of stay, says Hofmann.

Increasingly, insurance is covering medical procedures performed on an outpatient basis. Previously, these procedures were not covered unless they were done in the hospital.

"The cost of health care is high," says Hofmann. Most patients have some sort of insurance, but few have total coverage. "Many people postpone going to the doctor."

Community surgical centers, which perform outpatient surgical procedures, can provide a more efficient, less costly alternative to inpatient admission in a hospital, says Hofmann.

Hofmann says the increased emphasis on reducing expenses at Stanford hospital is designed to continue providing a cost-effective service without compromising the quality of medical care.

STANFORD--Patients who undergo coronary artery bypass surgery may experience symptoms of coronary artery disease again several years later, according to a recent Stanford study.

An earlier study of 350 former Stanford bypass patients showed that recurrence of symptoms is not uncommon. In a recent sample of 19 patients, representative of the larger group, studied six years after surgery, progression of disease was found in both bypassed and unbypassed vessels, accounting for the recurrence of symptoms.

Despite the recurrent angina, or chest pain, "most patients still retained some symptomatic benefit from their prior surgery," say the researchers. "Onset of these symptoms was usually gradual and it tended to occur late in the postoperative period, with an average onset of 54 months after surgery."

Authors of the report are Drs. Edward W. Robert, Diana F. Guthaner, Lewis Wexler, and Edwin L. Alderman of the division of cardiology and cardiovascular radiology at Stanford Medical Center. Supported in part by a grant from the National Institutes of Health, the study was reported at the annual meeting of the American Heart Association this week in Miami Beach, Fl.

When coronary arteries are narrowed, blood flow to the heart is reduced, producing symptoms such as angina pectoris (a type of chest pain long associated with coronary artery disease).

The bypass surgical technique, developed in 1968, involves removing a vein from the leg and attaching it to the aorta and the coronary artery beyond the obstruction. This bypass graft then increases the blood flow to the heart, relieving the angina.

Six years after surgery, 86 percent of the coronary artery grafts were still open in patients in the smaller study sample.

But more than half of the 19 patients showed progression of disease in either major unbypassed vessels or beyond the point where the bypass graft was made.

The authors conclude that the recurrent angina is more commonly associated with the progression of disease, rather than with failure of a graft.

All of the 19 patients noted improvement in their status one year after surgery. Five years later, only nine patients remained free of symptoms and the remainder reported moderate or severe angina.

The researchers reported that "despite the high incidence of deterioration, the symptoms were generally less severe than they had been before surgery...no patient considered himself clinically worse. The recurrent angina generally developed gradually after a long, relatively symptom-free, interval."

The physicians commented that the disease progression reflected risk factors that had originally caused the narrowing of the coronary arteries. More attention needs to be paid to such factors as smoking, hypertension, and fat consumption, they said. ### Mailed Thursday, Dec. 1, 1977

FOR IMMEDIATE RELEASE

STANFORD –

United Stanford Employees (USE) has withdrawn from union representation elections scheduled Feb. 2-4 at Stanford University Hospital and Clinics.

However, the election involving 33 licensed vocational nurses (LVNs) at the Hospital and Clinics will proceed as scheduled unless the California Licensed Vocational Nurses Association (CLVNA) decides to withdraw.

According to Gary A. Mecklenburg, administrator of Stanford Hospital and Clinics, the National Labor Relations Board (NLRB) granted USE's request to withdrawn from the elections, which would have involved approximately 1,200 service, technical and patient care employees, and pharmacists. These employees would have voted to determine whether or not they wished to select USE as their exclusive bargaining representative, or no union at all.

In the LVN election, LVNs will be able to choose between USE, the CLVNA, or "neither"—meaning no union.

Mecklenburg said in a letter distributed to Hospital and Clinics employees Tuesday, Jan. 31, that USE will now be prevented from petitioning for another election for service, technical and patient care employees, and pharmacists for at least six months.

In its newsletter also distributed to Hospital employees, USE claimed the elections were "postponed because of joint actions of Stanford and the NLRB."

USE, which is Local 680 of the Service Employees International Union, AFL-CIO, also claimed in the newsletter that a recent decision by NLRB regional director Michael Taylor for the elections to proceed did not provide the union with at least 30 days notice of the election. USE says this violates NLRB rules.

USE further claims that Stanford failed to deliver names of the voters until Jan. 16—three days late by NLRB rules. The NLRB rejected these contentions, however.

The elections which were scheduled this week were given the green light by the NLRB in early January.

According to Priscilla Wheeler, associate staff counsel at Stanford, the withdrawal by USE "brings an end to legal proceedings which have been ongoing between USE and Stanford since similar elections were held in 1975."

STANFORD--"Rape" will be the subject of the next lecture Thursday, Feb. 2, in a series on women and their health being presented at Stanford University Medical School.

The winter quarter series, which is being held on Thursdays at noon in Room M-104, is open to the public free of charge.

Barbaraterry Kurtz of the Santa Clara County Mental Health Department in San Jose will present the Feb. 2 lecture.

The lecture series is being sponsored jointly by the Department of Family, Community and Preventive Medicine of Stanford Medical School and the Stanford Center for Research on Women. It is being coordinated by Dr. Netta Grandstaff, senior research associate, and Leona McGann, assistant professor in Family, Community and Preventive Medicine.

According to Grandstaff, the series is designed to inform women and help them deal with health matters that may directly effect them. Lectures to date have dealt with alcohol abuse, psychotrophic drugs and menopause.

Future lectures include:

Feb. 9, "Battered Women," by Susan Hanks, a social worker in private practice in Oakland.

Feb. 16, "Childbirth: Alternatives in Care," by Margaret Bean, who is with the Mid-Wife Alternative Birth Center. She is also on the nursing staff at San Francisco General Hospital and in the Department of Obstetrics at the University of California in San Francisco.

Feb. 23, "Breast Care: Risk Factors for Breast Cancer," by Helen Crothers, assistant director of service and rehabilitation, California Division of the American Cancer Society.

March 2, "Female Sexuality" (lecturer to be announced).

March 9, "Aging Women and Health Care," by McGann and Dr. Halsted Holman, Guggenheim Professor, Department of Immunology, Stanford Medical School.

FOR IMMEDIATE RELEASE

STANFORD –

A new division of gerontology has been established in the Department of Medicine at Stanford University Medical Center.

Dr. Clayton Rich, vice-president for medical affairs and dean of the School of Medicine, made the announcement last week.

The division will be directed by Dr. Gerald M. Reaven, currently head of the division of endocrinology.

In 1975, 10.5% of the population of the U.S. was over 65 years old. That figure may reach nearly 12% by the year 2000, according to the U.S. Bureau of the Census.

As the number of older people increases, so does the need to attend to medical problems which are unique to their age group. However, according to the American Medical Association, only 27 medical schools in the U.S. report they offer teaching programs in geriatric medicine.

"The need for programs of this type is overwhelming," says Reaven, "but the response of medical schools so far has been inadequate."

Stanford's program combines research and teaching in both geriatrics and gerontology, he says. It will be affiliated with the Geriatric Research, Education, and Clinical Center (GREC) at the Veterans Administration Hospital in Palo Alto.

"Geriatrics focuses on the clinical problems of the older patient," says Reaven, who directs GREC. "Gerontology is the study of aging, as biological, sociological, and psychological processes."

The division will conduct clinical and basic biomedical research. Through a clinical service at the VA Hospital, it will also examine the problems of health care delivery among the aged.

Faculty will be recruited from various departments, such as psychiatry, pathology, and medicine.

Reaven, 49, has been teaching at Stanford since 1960. His major research interests include carbohydrate and lipid metabolism as it relates to diabetes and atherosclerosis.

One of his studies concerns the deterioration of glucose tolerance with age. Glucose tolerance is the ability of the body to absorb sugars from the blood. Other studies have related this phenomenon to the increased incidence of diabetes and heart disease among older people.

STANFORD--An international symposium to commemorate the achievements of Claude Bernard, a 19th century French physiologist, physician, and founder of modern experimental biology, will be held at Stanford University Feb. 10-12.

The three-day session, sponsored by the National Institutes of Health (NIH) and Stanford's Department of Physiology, will be held in Fairchild Auditorium at Stanford Medical School beginning Friday (Feb. 10) at 4 p.m.

Among the participants will be Francois de Laboulaye, French ambassador to the United States, and Nobel laureates Andre Cournand, Columbia University; Arthur Kornberg and Joshua Lederberg, Stanford; and Roger Guillemin, Salk Institute. President Richard W. Lyman of Stanford will welcome the guests at the opening session.

A number of leading scientists in the fields of biochemistry, biology, genetics, medicine and physiology will participate. They include Jean Bernard, University of Paris; J.P. Changeux, Pasteur Institute; Julius Comroe, University of California, San Francisco; Jack Orloff, National Heart Institute; Jonas Salk of the polio vaccine fame; Dan Tosteson, dean of Harvard Medical School, and others.

"Claude Bernard was one of the greatest figures in the history of experimental physiology and medicine," commented Dr. Eugene D. Robin, acting chairman of Stanford's Department of Physiology and organizer of the meeting.

"The purpose of the conference," he said, "is to review Bernard's accomplishments, to provide links between his work and modern developments in regulatory biology, and disseminate this knowledge."

The conference will consist of presentations by invited speakers. They will discuss their own work and review the "state of knowledge" in research areas where Bernard's contributions have been most significant--notably the internal regulatory mechanisms by which living things respond to changes in the environment. Among these are fluid and electrolyte balance, acid-base regulation, temperature regulation, and metabolic controls.

Bernard's most original contribution to theoretical biology was his concept of the "milieu interieur," the internal environment, said Robin. "He conceived of this as the blood, and much of modern medicine is based on studies of this fluid."

An important component of the symposium will be a review of the historical period--the cultural and scientific milieu--in which Bernard lived.

-more-

The conference will also focus on a current problem in regulatory biology--the relation between the various levels of organization at which biologic regulation occurs, and how these levels may be studied.

"Bernard's contributions," Robin noted, "are pertinent to many areas of current research and culture. The conference will serve as a link between the history of physiology, its present state and future directions."

***

The symposium is open to the medical community, scientists and students. It is free of charge, but advanced registration is required. Attendance applications should be submitted by Jan. 25 to Dr. Eugene Robin, Department of Medicine, Room C352, Stanford University School of Medicine (Tel. 497-5956).

FOR IMMEDIATE RELEASE

STANFORD –

New evidence that narcolepsy, a chronic sleep disorder, can be inherited in dogs has been reported to the American Narcolepsy Association (ANA) by Dr. William C. Dement, director of the Stanford Sleep Research Center.

The announcement was made last week at Stanford University Medical Center, during the world premiere of a film of narcolepsy, "Keep us Awake," presented by the ANA.

"All offspring of a pair of narcoleptic dogs have exhibited unequivocal signs of the disease," said Dement, "promising us a tremendous breakthrough in the search for the causes of narcolepsy."

Dement said the "reliably reproducing strain" of canine narcolepsy will provide a base for future observation and research.

Narcolepsy is a disease of REM (rapid eye movement) sleep which afflicts humans as well as dogs. Approximately 250,000 Americans have the disease, according to the ANA.

The disease is characterized by continuous sleepiness, and strange seizures of total paralysis, called cataplexy, said Dement.

"Very little is known about the cause of narcolepsy," he said, "and there presently is no cure for it."

In 1972 the disease was found to occur in dogs. Dement and his colleagues published their first report on canine narcolepsy a year later. Sincy then the Sleep Research Center has conducted a nationwide search for dogs afflicted with the disease.

The parents of the narcoleptic pups are two Doberman pinschers, Dobie and Bettina. Bettina gave birth to a litter of seven pups in December, 1977. Within six weeks all seven showed signs of narcolepsy.

"The development of narcolepsy in these pups is solid evidence of the genetic origin of the disease," said Dement.

Dement said narcolepsy may be the result of one or more recessive genes. That would explain why narcoleptic dogs, when mated to dogs which do not have the disease, do not produce narcoleptic offspring, he said.

Dement said he plans to test this theory by performing backcrosses, mating a normal son with his narcoleptic mother.

The breeding program is being directed by Dr. Luigi Cavalli-Sforza, professor of genetics at Stanford.

The narcolepsy studies have been supported by a grant from the National Institutes of Health.

ADVANCE FOR AM PAPERS, THURSDAY, JANUARY 19, 1978.

STANFORD –

Prof. Joshua Lederberg, Nobel Laureate and chairman of the department of genetics at the Stanford University School of Medicine, has been elected president of Rockefeller University, New York City.

He will succeed Dr. Frederick Seitz, who retired in 1976 but has continued in office until a search committee could recommend a successor.

Lederberg, 52, will be the institution's fifth president, a Rockefeller University announcement said Thursday, Jan. 19.

The announcement said Lederberg is one of the band of pioneers who have laid the foundation for developing the genetics of microorganisms into a comprehensive field of research.

Patrick E. Haggerty, chairman of the Rockefeller University board of trustees, also praised Lederberg for his leadership qualities, and "deep concern for strengthening communication between science and the society it serves."

Lederberg and his family plan to move to New York Sept. 1.

Rockefeller University is devoted exclusively to research, postdoctoral training, and graduate education primarily in the biological and biomedical sciences and the related behavioral, physical, and mathematical sciences.

Founded in 1900 by John D. Rockefeller, Jr., as the Rockefeller Institute for Medical Research, it has played a key role in bringing the U.S. to the forefront of modern medical sciences.

Lederberg, a native of Montclair, New Jersey, and a product of New York City public schools, Columbia University, and Yale, won a 1958 Nobel Prize "for studies on organization of the genetic material in bacteria."

He taught for 12 years at the University of Wisconsin before coming to Stanford School of Medicine in 1959. At Stanford he serves as Joseph D. Grant professor of genetics and director of the Lt. Joseph P. Kennedy, Jr. Laboratories for Molecular Medicine, dedicated to basic research in genetics, developmental biology, and neurobiology.

He also has related responsibilities for research programs in instrumentation, computers for laboratory use and in study of artificial intelligence, and the detection of planetary life.

Lederberg is a member of the National Academy of Sciences.

STANFORD--A new treatment center for cancer patients will be formally dedicated at Stanford University Medical Center in ceremonies Saturday, Jan. 21.

The Debbie Probst Oncology Day Care Center, which has actually been open and receiving patients since last fall, is located on the ground floor of Stanford University Hospital.

Director Dr. Saul A. Rosenberg says the center is helping Stanford provide "the most modern cancer care in a manner that is comfortable for the patient yet safe and efficient. Our concern is not only for the patient's survival but also the quality of survival."

The oncology center is named after the late Debbie Probst, a former patient and donor. It more than doubles the present cancer clinic facilities at Stanford.

The center, which cost approximately $300,000 including equipment, was funded by numerous individuals and organizations, including a grant from the National Cancer Institute.

Dr. Charlotte Jacobs, who is chief of the oncology center with responsibilities for clinic services, says the center has been specially-built with the cancer patient in mind.

"Our center is unique in the atmosphere we have created for the comfort and pleasant surroundings for the patient," she said. "This includes treatment rooms for long-term intravenous infusions, which normally in the past would have required hospitalization."

The oncology center also has a television monitoring system for regulating patient flow, patient blood counts and future appointments, television sets in some treatment rooms and a stereo system, she said.

Thirteen patients can be seen simultaneously in the new oncology center, which also has two special injection rooms, two long-term holding rooms and seven examination rooms.

The unit, which contains 5,000 square feet of space, also has its own pharmacy, where the drugs for treatment are prepared, a hematology laboratory, which does all of the blood work on patients, a social worker's station and patient records room.

Treatment at Stanford, which involves drugs, alone or in combination with surgery and radiotherapy, has been found to be successful in the management of certain malignant diseases, Rosenberg noted.

Last year the Division of Oncology, which handles chemotherapy, had approximately 7,000 patient visits. That number is expected to double with the opening of the Oncology Day Care Center.

Previously, the oncology clinic had to share quarters with other medical specialties at Stanford.

Jacobs said the Oncology Day Care Center is designed to meet the specialized needs of cancer outpatients and their doctors.

These patients may need to be seen daily for brief injections and blood counts, or they may require lengthy (six to eight hour) chemotherapy infusions (a procedure which has customarily involved hospitalization).

Many of Stanford's cancer patients are referred by physicians in the community and remain primarily under their care while their condition is being diagnosed or treated. ###

STANFORD--Thelma Moore, a housewife from a small town near Fresno and a mother of three, began radiation therapy at Stanford Medical Center last July.

The drive from her home to the hospital takes about five hours, says Mrs. Moore.

Initially, she and her family stayed in motels, but soon found that "the weekly charge of $120 to $140 a week, not including meals, used up our savings in a few weeks."

Now when Mrs. Moore arrives for a six-week session of therapy, she leaves her husband and children, and rents a room in a private home. American Cancer Society volunteers provide transportation to and from Stanford hospital. The cost of a room is about $35 a week, says Mrs. Moore, which represents a considerable saving.

Mrs. Moore is one of many outpatients seen at Stanford hospital who require long-term treatment but who live outside the immediate area, according to Margie Lutzker, a clinical social worker in the division of radiation therapy.

When patients and their families arrive at Stanford, they look for housing close to the hospital. If they come by plane or do not drive, getting to and from the medical center poses a major problem because of the lack of adequate public transportation.

Unlike some other major medical centers which are surrounded by large old homes with rooms to rent, housing in the Stanford area is scarce and expensive, says Lois Christopherson, chief clinical social worker in the department of surgery.

Stanford hospital does not maintain a special facility to house outpatients and their families as do some large teaching hospitals. For example, at the University of Minnesota, patients and families may rent rooms, at a cost of $8 to $10 a day, in a converted dormitory adjacent to the university hospital, according to Terry Severson of the University of Minnesota Hospitals.

But at Stanford the problem of finding suitable housing for patients is complex, social workers agree, and there are no simple solutions.

For patients without private transportation, motels on El Camino Real, where there is regular bus service, seem to be the most convenient choice. Those who drive and have access to a car may try to rent a furnished studio apartment.

Patients who cannot afford to maintain two residences look for rooms to rent.

"Patients living in motels and furnished apartments must cope with loneliness and isolation in unfamiliar and sometimes cheerless surroundings," says Lois Christopherson. On the other hand, those living in private homes may lose privacy and be faced with the added burden of "keeping up a brave front," she notes. Unless their home is unusually large, the host family faces the loss of some privacy and, in addition, may find that the time and support patients require, create difficulties in their own family.

The task of finding accomodations for patients in private homes falls largely upon the hospital social workers who rely on an informal network of friends, nurses, aides and other employees to keep them informed of what is available.

Local church groups are participating in a program to provide housing for patients and their families among congregation members, according to Dr. Ernle Young, chaplain to the medical center. -more-

"Originally the program was aimed at providing support for the families of patients who sit for hours and hours in waiting rooms," says Nan Wentworth, a coordinator for Valley United Presbyterian Church, but the urgent and unmet needs of the patients, themselves, have caused a shift in focus.

When a young South American woman working on the Peninsula became ill, she found herself jobless and with no place to stay. During a five month period while she received radiation therapy, the church referral service placed her in three different homes. Since then, she has found permanent housing, but still remains in close touch with her former host families, visiting with them during Thanksgiving and the Christmas holidays, according to Wentworth.

Each day about 130-150 patients are treated in the division of radiation therapy, reports Lutzker. Approximately ten percent of the patients drive more than two hours a day to and from therapy, which is not easy to do when one is sick and fatigued, notes Lutzker. About a quarter of all patients rent facilities or stay with relatives or friends in the area. Length of total treatment, including chemotherapy, can range from several weeks to a year.

Patients who come to the medical center for evaluation as potential heart transplant recipients number about fifty a year, says Christopherson. Of these, about forty are from outside the immediate area.

Those found to be suitable candidates for a transplant wait several days to months for the operation. If their home town has access to good transportation, the waiting period may be spent at home. If not, they must remain in the Stanford area. After they leave the hospital, they remain as outpatients for about two months before they are ready to go home, says Christopherson.

"Heart transplant candidates and their families are warned about the poor housing and transportation situation before they come to California and are given maps, motel and apartment lists when they arrive," notes Christopherson. "Even so, our lack of nearby, low-cost housing does pose a serious additional stress for these patients."

The need for some kind of housing on campus for outpatients and their families is recognized by virtually all of those involved in their care. Stanford University has considered the possibility of building a hoptel on campus, but the project has been deferred because of a lack of funds.

When asked about interim solutions, various suggestions have been offered.

Dr. Young believes an older home on campus might be converted into outpatient housing. It could be run by students and serviced by a shuttle bus.

Christopherson wishes that donations to the University might make it possible to purchase one of the hotels in downtown Palo Alto so that the rooms and club kitchen facilities could be used, at cost, by medical center patients and their families.

Lutzker would like to see a facility with access to transportation made available at a nominal cost to patients who must remain in the area longer than two weeks. Ideally, it would offer a range of accommodations--food preparation, cleaning and laundry services--according to individual patient's needs.

Development of a trailer park is another pressing need, according to Young. Since the least expensive way of living away from home is in a mobile home, many outpatients and their families arrive in trailers. Local trailer parks are often full, however, and they must resort to using parking lots and side streets--a practice which is illegal notes Hilary Ryniewicz, director of safety and security at the hospital.

Individuals who have rooms or furnished apartments which they would like to make available to patients and their families, may send such listings to the Stanford Medical Center News Bureau, Room TC-135, or phone 497-6911.

FOR IMMEDIATE RELEASE

STANFORD –

A new division of family medicine has been established in the Department of Family, Community, and Preventive Medicine at Stanford University Medical Center.

Dr. Clayton Rich, vice-president for medical affairs and dean of the School of Medicine, announced its creation.

"The creation of a division of family medicine at Stanford is the culmination of efforts over the past 10 years," said Dr. Count D. Gibson, Jr., Department chairman.

"Stanford now joins all of the other medical schools in California in committing itself to teaching family medicine," he said.

The new division is directed by Dr. William C. Fowkes, Jr., associate professor of clinical family medicine and clinical medicine. Fowkes, 47, currently directs the residency program in family medicine at San Jose Hospital.

Fowkes, who received his M.D. from Stanford in 1955, also coordinated Area III of the now defunct California Regional Medical Program for several years.

"The family physician is not just another name for general practitioner," according to Dr. Lee Blanchard, clinical associate professor at Stanford.

"The old GP was concerned about taking care of all disease processes. Family practice, on the other hand, emphasizes the person, rather than the disease process. The family physician provides continuous, comprehensive care for every member of the family, from infant to the aged."

In addition, the family physician coordinates the services of consultants and allied health personnel in the care of his patients, he said.

Blanchard, a 1937 graduate of the Medical School, practices family medicine in San Jose. Formerly he was secretary to the residency review committee for family practice of the American Medical Association (AMA). He is currently on the Departmental staff, assisting in program development.

Family medicine was recognized as a specialty by the AMA in 1969. But there still is a great need for physicians who provide primary care, said Fowkes. "Several hundred counties in the U.S. have no doctors at all," he said.

The Mid-Peninsula has one of the highest densities of physicians in the country, yet family physicians in the area are swamped with patient loads, said Gibson.

"In this very overspecialized era, families cry for a physician who will specialize in them," he said.

Fowkes said the new division will provide training in family medicine at all levels.

Medical students with few clinical skills will be able to observe the family practice of community physicians. As they become more skilled, they can work with the physicians in preceptorships.

This part of family medicine training will continue to be directed by Leona M. McGann, assistant professor in the Department of Family, Community, and Preventive Medicine.

Recently the Department received a $106,000 renewal grant from the Department of Health, Education, and Welfare to support the preceptorship program.

Teaching duties in the division are shared by Dr. Joseph R. Hopkins, clinical assistant professor. A 1973 graduate of the Stanford Medical School, Hopkins directs the Mid-Peninsula Health Service.

Education of residents will take place in a community hospital. Gibson said the Department plans to arrange a cooperative teaching and research arrangement with San Jose Hospital.

"Residency education in community hospitals is appropriate because this is where families come for treatment, rather than to tertiary care centers like Stanford," he said.

Gibson said that while family physicians are relatively few, "there is a new surge of young doctors with broad commitments on the way.

"The key to a rational health care system is a strong cadre of family physicians throughout the country who can help create appropriate patterns of care in collaboration with specialists," he said.

FOR IMMEDIATE RELEASE
STANFORD –

Hepatitis B infection is a significant occupational risk for physicians and other health-care workers, according to a study published in the recent *Journal of the American Medical Association.*

The risk of acquiring this viral infection was more than five times greater for physicians than for a comparison group of volunteer blood donors, according to researchers from the Center for Disease Control in Phoenix.

A coauthor of the report, Dr. Joseph L. Smith, now at Stanford University School of Medicine, says that exposure to blood and blood products, rather than patient contact, appears to be the major risk factor.

Hepatitis viruses cause inflammation of the liver. There are at least three types: hepatitis A which usually occurs in epidemic fashion and is associated with poor hygiene conditions; hepatitis B which is commonly associated with blood transfusions or unsterile needles used in injections; and nonA-nonB type which has been described following blood tranfusions, but can also occur as sporadic community-acquired illness.

About 10% of those who develop acute hepatitis B continue to carry the virus in their liver and blood.

The researchers surveyed 1,200 physicians attending American Medical Association conventions in 1975 and 1976. Physicians were tested for antibody to hepatitis B virus, which would indicate if they had ever been exposed to the virus. They were not tested for evidence of current infection.

Smith says that doctors with antibodies to the disease are noninfectious, and will not pass the infection on to patients.

According to the report, evidence of previous infection was found in 18.5% of the physicians who volunteered for the study. The prevalence in the nonphysician group was 3.5%.

The report indicated that only 31% of the physicians with evidence of previous infection recalled having the disease. "This suggests that a majority of cases were either asymptomatic, or symptoms were unrecognized," says Smith.

Purpose of the survey, he says, was to determine if particular types of physicians are more at risk than others, and might benefit most from immunization with vaccine now being developed in U.S. laboratories.

They found that surgeons and pathologists had the highest prevalence rates. Twenty-eight percent of surgeons and 27% of pathologists had evidence of previous infection.

Infection rates for those in internal medicine, anesthesiology, obstetrics and gynecology, pediatrics, and family practice were similar to those for all physicians.

In addition, they found increased frequency of exposure for those practicing in large metropolitan areas. Another finding was that Oriental physicians were almost three times as likely to have the antihepatitis B antibody as whites.

The rate of exposure was highest in the early years of clinical activities, including the years of hospital-based postgraduate training and the early years of private practice.

The report concluded that "more effective control measures are needed to prevent occupationally acquired infection among health care professionals. . . . The best approach will likely be through vaccine-induced active immunity."

Smith, a postdoctoral fellow in the Division of Infectious Diseases, works with Drs. Thomas Merigan and William S. Robinson on treatment of chronic hepatitis B infections with antiviral agents, such as interferon.

Coauthors of the report are Drs. Alexander E. Denes, James E. Maynard, Kenneth R. Berquist, and Irene L. Doto of the Center for Disease Control; and Dr. Asher J. Finkel of Chicago.

STANFORD--Dr. Edgar Haber, a Harvard cardiologist well-known for his biochemical and immunological work, will present the annual John Kent Lewis Memorial Lecture at Stanford University School of Medicine on Monday, Jan. 23.

Dr. Haber will discuss "Specific Antibodies as In Vivo Diagnostic and Therapeutic Agents" at 4:30 p.m. in the Fairchild Auditorium. Physicians and other health professionals in the community are invited to attend.

Chief of the cardiac unit at Massachusetts General Hospital, Dr. Haber is also professor of medicine at Harvard Medical School.

His work has focused on developing radioimmunoassays for drugs and hormones, and their applications in understanding the basic pathological mechanisms in hypertension.

He has also developed radioactive labeling techniques enabling doctors to identify damaged heart muscle.

Dr. Haber received his A.B. from Columbia College (1952) and M.D. from Columbia College of Physicians and Surgeons (1956). He did postgraduate work at Massachusetts General Hospital, and has been on the faculty of the Harvard Medical School since 1963.

The John Kent Lewis Lectures are presented annually in honor of the former chief of the Stanford Medical Service at San Francisco General Hospital. A 1922 graduate of Stanford Medical School and noted pioneer in heart research, Lewis died in 1961.

###

STANFORD--The Division of Ophthalmology at Stanford University Medical School has been awarded a grant of $5,000 from Research to Prevent Blindness, Inc.

According to Dr. Jules Stein, chairman of the organization, the grant is one of 50 made in 1977 to medical institutions in the U.S. by the New York-based voluntary foundation.

Dr. A. Ralph Rosenthal, head of the Division of Ophthalmology, said the unrestricted grant is designed to stimulate and support the total research effort.

"The funds are especially valuable," he said, "because they encourage pioneering research, the exploration of the most promising new concepts."

Ophthalmology research at Stanford is primarily in the fields of glaucoma, ocular toxicology and corneal physiology, said Rosenthal.

FOR IMMEDIATE RELEASE

STANFORD –

Stanford University Medical Center officials have denied charges made by Dr. Robert Weinmann, president of the Union of American Physicians, Local 7402, that Stanford charges improperly for services to Medicare patients.

Weinmann distributed copies of documents at a press conference Monday, Jan. 9, showing that both Blue Cross and Blue Shield had sent notice of payments to a patient concerning a single visit to a Stanford Clinic in July 1977.

Blue Cross and Blue Shield are under contract with the federal government to handle different parts of the Medicare program in Northern California. Blue Cross is responsible for "institutional reimbursement" and Blue Shield is responsible for professional fees (doctor bills).

"The two notices sent to the patient result from long-standing billing procedures required of us by Medicare for services rendered on an outpatient basis" said James H. Stanford, Medical Center Finance Director. "It does not represent improper billing."

For most Medicare patients seen in the Clinics, Medicare will pay a professional fee to the faculty physicians for the services they render, according to Medical Center officials. These fees are paid by Blue Shield.

However, there are some costs of operating the Clinics which Medicare will not reimburse on a professional fee basis due to restrictions in the Medicare law. Since Medicare will not pay professional fees to cover these costs, it instead reimburses the Medical Center for the actual costs incurred. This reimbursement is paid by Blue Cross.

Stanford agrees that the current system may be confusing to Medicare patients since both Blue Cross and Blue shield send notices of payments.

This process was established and approved several years ago by Medicare officials at the intermediary level and at the Bureau of Health Insurance in Baltimore, the federal government agency responsible for administering the Medicare program.

STANFORD--Employee elections at Stanford University Hospital and Clinics, which National Labor Relations Board (NLRB) officials had considered postponing, are officially on again.

The secret ballot elections, to be held Feb. 2-4, will allow eligible service, technical and patient care employees to decide whether or not they prefer United Stanford Employees (USE), as their exclusive bargaining representative. Eligible licensed vocational nurses (LVNs) will also be able to vote on whether they wish representation by either the California Licensed Vocational Nurses Association, or USE.

In a letter sent today (Tuesday, Jan. 10) to Stanford Hospital and Clinics employees, hospital administrator Gary A. Mecklenburg says the elections were ordered to proceed by Michael Taylor, director of the NLRB's Region 32.

USE, which is Local 680 of the Service Employees International Union, AFL-CIO, had filed an unfair labor practice charge last spring. It claimed that an Employee Opinion Survey distributed at Stanford Medical Center was designed to influence employees whether to select USE as their collective bargaining representative. Because of this charge the NLRB's regional director had considered postponing the elections.

Taylor has now directed the elections to go ahead as scheduled, and says that distribution of the survey would not affect the employees free choice in such balloting.

When the survey charge was initially filed by USE, the NLRB's regional office found the charge meritless and refused to issue a complaint on the matter so that the legal issues could be heard before an administrative law judge.

In his letter to employees, Mecklenburg says the medical center's administration "agrees with the regional director (Taylor) that distribution of the Employee Opinion Survey would not affect the exercise of employee free choice in such an election."

He added, "(The administration) continues to believe employees should have the opportunity to express their preference in the election in accordance with (the) arrangements and schedule agreed upon by the medical center, the NLRB and USE last summer."

Similar elections were actually held in April, 1975, in the hospital and clinics. Balloting was conducted by the NLRB and more than 1,000 of 1,200 eligible employees voted overwhelmingly to reject any union representation.

Following this election USE filed unfair labor practice charges and election objections.

USE charged, in part, that two minority employee groups--La Alianza Latina and the Black Advisory Committee--were unlawfully assisted and dominated by the hospital. Both employee groups have been active in affirmative action efforts.

USE also protested alleged time off to attend meetings and the use of hospital meeting rooms for members of La Alianza Latina and the Black Advisory Committee by the hospital.

The NLRB rejected USE's claim that the groups had been "dominated" by the hospital. Last summer, the medical center, NLRB and USE entered into a settlement resolving the outstanding election charges and objections. The new election dates were then set as a part of this settlement. ###

STANFORD –

Stanford physicians have issued a warning against collecting and eating wild mushrooms, as a result of several serious cases of mushroom poisoning admitted to Stanford University Hospital recently.

The patients, five young adults and two children, remain in guarded condition after eating the species *Amanita phalloides.* This species grows in abundance in the San Francisco Bay Area after the fall rains and through the winter and spring.

Dr. Mark G. Perlroth, associate professor of clinical medicine, said that the *Amanita* varieties can be distinguished from harmless mushrooms only with difficulty. He urged that mushrooms be bought from markets, and not picked wild.

Effects of mushroom poisoning, says Perlroth, may lead to severe liver and kidney damage and possible death.

As the poison is absorbed by the body, a patient may have no symptoms during the first few hours, he said. Then, 6 to 24 hours later, victims may suffer from nausea, vomiting, abdominal pain, and diarrhea.

As the toxin binds to the cells in the liver, there is little the body can do to get rid of it. After a period of apparent improvement, some two to nine days after ingestion, patients may begin to show signs of liver, kidney, and central nervous system damage, with life-threatening consequences.

Evidence of the effects of the mushroom poison on the patients' nervous system include confusion, coma, visual disturbances, and abnormal reflexes, said Perlroth.

Recovery depends upon the amount of toxin the body absorbs, as well as the variety of mushrooms eaten, said the physician.

He noted there is no specific therapy for mushroom poisoning other than careful supportive care. He said that Stanford phsycians are treating the current patients with thioctic acid, an experimental substance obtained from National Institutes of Health laboratories. Thioctic acid acts on the metabolism of cells in the liver and is thought to be useful in treating the poisoning.

Perlroth noted a further problem for amateur mycologists—the toxin content within various species of mushrooms may vary widely with the seasons, environment, and age of the mushrooms. One which is harmless at one time and place might be lethal at another, he said.

STANFORD--Leonard Lopez has been appointed associate administrator of Stanford University Hospital and Clinics, beginning Jan. 16.

Since 1974 Lopez has served on the management staff at The Johns Hopkins Medical Institutions where he recently was administrator of the Department of Laboratory Medicine.

According to Gary Mecklenburg, administrator of Stanford Hospital and Clinics, Lopez will have responsibilities for a number of patient-related services. These include the Drug Assay Lab, EEG and EMG Labs, Neuromuscular Lab, Immunology, Infection Control, Cardiology Services, Core Clinical Laboratory, Infectious Diseases Lab, Pathology, Radiology, Transfusion Service and the Virology Lab.

From 1969 to 1974 Lopez served at Washington University Medical School in St. Louis, Mo., where he was supervisor of the Division of Nuclear Medicine and director of the post-graduate program in nuclear medicine technology at Mallinckrodt Institute of Radiology.

He is a certified medical technologist (ASCP), which he received at Northwest Texas Hospital in Amarillo. In addition, he was certified as a nuclear medicine technologist at Washington University Medical School.

Lopez received both his B.S. degree in business administration and his master's in health administration from Washington University.

He is married and has two children.

STANFORD--A three-year, $300,000 grant has been awarded to Stanford University Medical Center for the training of emergency medical personnel.

The grant, which was awarded by the Department of Health, Education and Welfare (HEW), will fund the Stanford METRO Program (which stands for Medical Emergency Training and Resource Opportunity).

According to Dr. Michael Eliastam, director of emergency services at Stanford, METRO involves training for physicians in emergency care, plus courses for physicians, nurses, paramedics, and instructors involved in all phases of emergency medicine.

At the same time, Eliastam noted, Stanford will participate in regional testing programs for emergency medical technicians, or paramedics, in cooperation with the San Francisco regional governmental agency known as ABAG (the Association of Bay Area Governments). ABAG recently received a grant from the Kaiser Foundation to establish testing procedures for emergency skills.

The inclusion of these training programs will coincide with the development of a residency program to train emergency medicine physicians at Stanford, Eliastam said. The first group of resident physicians will begin their training July 1, completing a two-year post-internship residency.

Stanford already operates a comprehensive training program for paramedics. It is the major certified paramedic program in Northern California with paramedic graduates presently employed by fire departments, law enforcement agencies, ambulance companies and the National Park Service.

Under the METRO program, Stanford will serve as a resource center for professionals in the emergency care field. It will provide continuing education programs for these professionals, as well as serving as a circulation center for emergency medicine, periodicals, journals and audiovisual aids.

STANFORD--A series of weekly public lectures on women and their health will be presented during the winter quarter at Stanford University School of Medicine.

The free lectures will be presented each Thursday at noon in Room M104 of the medical school.

"Family Planning: The Status of Birth Control" will be the subject of the first lecture Thursday, Jan. 5, by Dr. Katherine Finseth, a consultant in Health Sciences Research and director of the Family Planning Center in Santa Clara County.

A Harvard graduate, Finseth formerly served on the faculty at Yale Medical School.

According to Dr. Netta Grandstaff, senior research associate in the Department of Family, Community and Preventive Medicine in the medical school, the women and health care series is being sponsored by the Stanford Center for Research on Women, and Family, Community and Preventive Medicine.

She noted that each of the lectures will be presented by "recognized authorities in their designated fields."

Future topics for the Thursday series include: "Childbirth: Traditional and Current Modes of Care," "Menstruation, Menopause and the Use of Estrogen," "Women in Psychology: Psychotrophic Drug Use," "Rape," "Battered Women," "Women and Alcohol Abuse," "Female Sexuality," "Breast Care and Breast Cancer," and "Aging Women and Health Care."

STANFORD--Plastic surgeons have now developed techniques to reconstruct the human ear, a procedure long considered to be the most difficult operation they might attempt.

The best method involves transplanting the patient's rib cartilage to form the contours of the ear, according to Dr. Burt Brent, assistant clinical professor at Stanford University Medical Center.

During surgery, Brent obtains several inches of flexible rib cartilage, carves and sculpts it to form an ear, then implants it under the skin.

Brent has successfully performed more than 150 ear reconstructions in this way during the last four years in patients referred to him from throughout the world.

One of his more well-known patients is J. Paul Getty III, whose kidnappers received $3 million ransom in Italy upon severing his ear four years ago and sending it to his family.

Getty, 21, has undergone two operations this year, says the plastic surgeon, and some further work will be necessary to complete the restoration. His hearing was not impaired in the incident.

One child in every 6-10,000, says Brent, is born without an ear. When caused by birth defect, absence of the ear occasionally results in a hearing deficit, which can be improved by a combined effort with an otolaryngologist.

Often a dramatic psychological change occurs in patients after the restoration, says Brent. Young Getty, whom Brent describes as a pleasant, cooperative patient, has begun to "mature" since the surgery began, he says.

Brent, who originally thought of pursuing a career in art, enjoys the technical challenge of his work, but says, "the real thrill is helping the patient and his family psychologically."

In a typical case, a young boy born without an ear may appear well adjusted until he begins school, says Brent, when cruel ridicule begins. "I have seen many teenagers with uncorrected congenital defects who also have severe emotional scars."

For that reason, Brent likes to perform the surgery before a child begins school. He has developed the technique to routinely perform the cartilage graft at age four.

A child's ears are 85 percent grown to their adult size by age three or four, he says. Since transplanted cartilage will grow slightly in a youngster, the reconstructed ear can be matched to the opposite normal ear so that both will be proportionate in size when the child is an adult.

Brent has performed the reconstruction on children as young as three and adults as old as 58. "The only restriction in young patients is the size of the rib cartilage which serves as the sculpting medium," he says.

In the first and major stage of the operation, Brent removes several inches of cartilage from the front portion of the patient's ribs. This flexible portion of the rib allows expansion and contraction of the chest wall during breathing. Removal of several rib cartilages merely creates additional "floating ribs," and does not create a functional disability, says the surgeon. -more-

While the patient is still anesthesized, the surgeon sculpts the flexible, elastic-like cartilage to form an ear framework, then implants it under the skin where the ear should be. He refers to subsequent operations as minor "touch-ups" and refinements.

Brent says he "became intensively involved in this fascinating facet of reconstructive surgery because of my hobbies in art and sculpture, and also because I feel an obligation to help the many children with this deformity."

Although he enjoys all aspects of plastic surgery, the majority of his practice is limited to the reconstruction of missing body parts.

Born into a medical family, Brent decided reconstructive plastic surgery would enable him to use his artistic abilities while also helping people. His artistic hobbies include painting, sculpting, and drawing his own medical illustrations. On completion of his general surgery training he took one year off to restore valuable artifacts in museums in Britain and Spain before returning to complete training in plastic surgery.

Ear reconstruction was first illustrated in 1597 by Tagliacozzi, and Italian surgeon. Brent cites Dr. Radford Tanzer, Professor Emeritus of Dartmouth Medical School, as the father of modern day ear surgery.

Methods other than use of rib cartilage have been developed by several other surgeons, including the use of a silastic ear framework developed by Dr. Thomas Cronin of Houston, and the use of ear cartilage from the opposite normal ear by Dr. Mark Gorney of San Francisco, a Stanford clinical faculty member.

Brent received his M.D. in 1963 from the Chicago Medical School and had plastic surgery training at Loyola University.

There are far more adults with missing ears than children, he says, due to auto accidents, dog bites, burns, and postsurgical deformities caused by diseases such as cancer. He developed techniques for work with adults at the Hines Veterans Hospital in Chicago, where he treated many Vietnam victims.

Prior to joining Stanford, Brent received a fellowship for further study at Canniesburn Hospital in Glasgow, Scotland, which is the largest plastic surgery unit in the world.

Since completion of his training in 1973, Brent has received several national awards for his work. This year he was awarded first prize in clinical research from the Educational Foundation of the American Society of Plastic and Reconstructive Surgery. The research concerned growing special skin grafts which grow their own underlying cartilage support. Coauthor of that work is Dr. Richard Ott, a Stanford resident in plastic surgery.

Three years ago, Brent received the same prize for his work in ear reconstruction.

Brent devotes at least two days each week to laboratory investigation of cartilage and other tissue transplantation, which he calls the "building blocks to successful clinical work with patients.

"The longterm result depends upon living tissue," he says. "And in this way ear reconstruction differs from basic woodworking...just as the sculptor must know the woods he uses--their grains, consistency, stresses and colors--so we must know the basic human tissue we work with, to create a pleasing, lasting reconstruction."

FOR IMMEDIATE RELEASE

STANFORD—

Stanford University Medical Center officials Friday, Feb. 24, said they have started a review of the policies regarding professional staffing and billing in the Emergency Department, and have delayed billing doctors' fees until the review is completed.

Dr. Lawrence Crowley, chief of staff and deputy dean of the School of Medicine, said the review will be completed in about two weeks.

He explained the review was part of a normal procedure made necessary by recent Medicare rulings. He also expressed hope that the review would clear the air concerning allegations of double-billing made last fall by the Union of American Physicians (UAP).

UAP had charged that Stanford billed patients for services by teaching physicians when all the work had been performed by interns and residents.

Stanford had replied that billings for Medicare and Medi-Cal patients have been audited regularly by the government's fiscal agents and were in full compliance with the guidelines then in force for teaching physicians.

Crowley said, "Quite aside from federal guidelines, it is Stanford's policy that teaching physicians should charge a fee only if they have provided an identifiable medical service to the patient. They must provide the service personally or in a direct supervisory role," he said.

At Stanford, a teaching institution, the rendering of patient services includes the participation of residents as well as faculty attending physicians.

Crowley said the new Medicare rulings became effective Feb.15. They require different documentation of a teaching physician's participation in the care of the patient than previously existed.

He said the new documentation requirements were spelled out in detail in a memo sent to the faculty of the clinical departments recently. These must be met before payment by the federal programs can be justified.

Crowley said that although the ruling applies to Medicare at this time, "we wish to maintain the same standards of care and a consistent policy regarding documentation in the rendering of services for all patients regardless of the source of payments."

STANFORD--Six women scientists at Stanford University School of Medicine doing basic research in the fields of immunology, molecular biology and physiology have been named Katharine McCormick Scholars.

The postdoctoral fellowships honor the late Katharine Dexter McCormick who left a large bequest to the Medical School, particularly "for the encouragement and assistance of women in pursuing the study and teaching of medicine and medical research."

The new awards bring to 26 the number of women scientists who have been supported by the Stanley McCormick Fund since its inception in 1969.

The McCormick Scholars are: Jeanette Chen, Department of Physiology; Jane Gillen, Genetics; Diane Rein, Pharmacology; Janet Schottel, Medicine and Genetics; Virginia Scofield, Pathology; and Rhona Simmons, Pathology.

* * *

Further information about the research of the McCormick Scholars follows:

Jeanette Chen received her Ph. D. in psychology from Rutgers University and is a fellow in the laboratory of Dr. Julian Davidson in the Department of Physiology.

Chen is studying sexual differentiation and hormonal changes during development in squirrel monkeys. In another project she observes how prenatal alcohol treatment of female rats affects sexual differentiation among the offspring.

Jane Gillen received her Ph. D. in bacteriology from the University of California at Berkeley and is a fellow in the laboratory of Dr. A. T. Ganesan in the Department of Genetics.

Gillen is studying the initiation of DNA replication in bacteria and bacterial viruses. She is working with a virus that infects a particular bacterium. The virus apparently modifies the replication machinery of the host cell in such a way that it will specifically replicate the virus's genetic material.

"This kind of control mechanism may also play a role in certain viral infections of animal cells," Gillen said. "By studying this process in a relatively simple bacterial system, we hope to shed light on similar processes in higher organisms."

Diane Rein received her Ph. D. in developmental biology from the University of Cincinatti and is a fellow in the laboratory of Dr. Henry Epstein in the Department of Pharmacology.

Rein, who works with nematodes, or roundworms, is studying the muscle structure of a particular mutant in which abnormal muscle development results in gradual paralysis.

"With a life cycle of 10 days, the nematode provides a model system for determining the biochemical and molecular mechanisms of this process of paralysis," she said. The results of such research may provide some insights into understanding the development of muscular dystrophy in human beings, Rein noted.

Janet Schottel received her Ph. D. in biology from Washington University in St. Louis, Missouri, and is a fellow in the laboratory of Dr. Stanley Cohen in the Departments of Medicine and Genetics. She is studying plasmid-determined heavy metal resistances in bacteria.

"Plasmids are small circles of hereditary material (DNA) that are present in many kinds of bacteria," she explained. Some plasmids carry genetic information that causes bacteria to develop resistance to a variety of antibiotics and heavy metals such as silver and mercury salts.

-more-

Silver salts are used in the treatment of burn wounds, Schottel noted. Mercury has many industrial uses and, as a consequence, is the source of the present mercury pollution problem.

"Understanding the mechanisms by which bacteria develop resistance to heavy metals is of great clinical importance," according to Schottel.

Virginia Scofield received her Ph. D. in biological sciences from the University of Texas at Austin and is a fellow in the laboratory of Dr. Irving Weissman in the Department of Pathology.

Scofield is studying the mechanisms and molecular structures of transplantation reactions in a class of animals called protochordates.

She is studying marine animals known as tunicates at the Hopkins Marine Station of Stanford University.

"By studying the gene systems of these animals, we hope to learn more about the evolution of gene systems which control transplantation reactions and immune responses in vertebrates," said Scofield.

Rhona Simmons received her Ph. D. in medical microbiology from Stanford University and is a fellow in the laboratory of Dr. Errol Friedberg in the Department of Pathology. She is studying the enzymology of DNA repair in bacteria.

"DNA damage can occur for many reasons, including exposure to X rays, ultraviolet light and various chemicals," Simmons explained. Certain enzymes recognize when an alteration has taken place in the DNA, and correct it. Abnormal repair occurs when the enzymes that should recognize the damage are absent, or are present, but not capable of functioning normally.

"This abnormal repair may result in the formation of mutant cells," Simmons noted. "Such mutations may possibly be linked to the production of cancerous cells."

STANFORD--Stanford faculty and staff who have mild hypertension may participate in a new study involving non-drug management of the disorder.

According to Dr. Stephen P. Fortmann of the Stanford Heart Disease Prevention Program, the benefits and risks of lifelong drug therapy for mild hypertension are still under debate. An effective non-drug program might be useful for such individuals, he says.

To participate in the study, volunteers from the Stanford campus and surrounding community should have blood pressure measurements of 145-165 systolic and 85-105 diastolic. Volunteers, between 21 and 65 years of age, must not be taking blood pressure medication.

After initial screening, volunteers will be randomly divided into two programs. The behavioral therapy program involves weight control, salt restriction, and relaxation techniques. The second program involves intensive monitoring of blood pressure during the study.

Stanford faculty and staff who participated in the risk survey done in 1973-75 and whose blood pressure at that time fell within the mild hypertensive range, will be invited by letter and telephone to participate.

Volunteers who are selected will need to visit the Stanford Heart Disease Prevention Program clinic on Welch Road several times for check-ups, to measure blood pressure, weight, blood lipids, and take urine tests and an electrocardiogram.

Participants will be given results of the check-ups at no cost.

According to Fortmann, hypertension is one of the major causes of cardiovascular diseases. "As we are continuously reminded of the dangers of chronic exposure to chemicals of many sorts, we must question the wisdom of lifelong chemotherapy for patients with mild hypertension.

"At present, people with mild hypertension are either followed through time or given drugs," says Fortmann. "We want to compare an intensive follow-up procedure with certain non-drug treatment--diet, weight control, and relaxation therapy. Although these can lower blood pressure, no one has compared a combination of these techniques with a follow-up in a group not taking medications."

The behavioral group and their spouses will attend 10 weekly 90-minute group sessions, where they will be taught relaxation therapy, moderation of salt intake, and weight control.

Homework assignments will be given, including daily practice of relaxation for 20-30 minutes, and daily monitoring of eating habits. -more-

The monitoring group will receive four weekly evaluations every three months involving blood pressure determinations and blood and urine tests.

A recent Stanford study of the effects of relaxation therapy with patients on medication found that it resulted in a significantly larger decrease in systolic pressure compared to drugs alone, and a trend toward a larger reduction in diastolic pressure. In that study, therapy involved daily home practice of progressive relaxation, guided by a cassette tape played while relaxing, and by instructions given during weekly sessions with a therapist.

The hypertension study is an outgrowth of the Three Communities Study, done under the direction of Dr. John Farquhar, in which a mass media campaign aimed at lowering residents' risks of heart disease.

According to Farquhar, a program such as the hypertension study could be applied in a community-level intervention for the prevention of hypertension and cardiovascular disease.

"If effective, this method could provide the cornerstone for a public health approach to blood pressure control," says Farquhar.

Persons interested in more information about the study, or who think they may be eligible, may call Dr. Fortmann or Dr. Rolf G. Jacob at 497-6051.

FOR IMMEDIATE RELEASE
STANFORD –

Stanford researchers have found that the measurement of the magnetic fields of the heart provides information about the conduction of impulses not reflected in conventional electrocardiography.

The technique may increase reliability in the diagnosis of heart disease.

Results of initial clinical studies using a SQUID differential magnetometer were reported in the Dec. 16 issue of *Science* magazine by Drs. William Barry, William Fairbank, Donald Harrison, and their associates.

The device measures magnetic fields produced by the flow of charged particles, called ions, through heart muscle cells. Ionic flow, which occurs during muscle contraction, also generates the electric fields measured in the electrocardiogram (EKG).

The differential magnetometer cancels out exterior magnetic fields which otherwise would interfere with the reading of the heart fields.

SQUID stands for superconducting quantum interference device. It amplifies the cardiac magnetic signals so they can be measured. The signals are processed and displayed in graphic form similar to the EKG.

According to Dr. Harrison, head of the division of cardiology and holder of the endowed William G. Irwin Professorship of cardiology, the EKG cannot diagnose certain heart conditions which involve abnormal electrical conduction through the heart.

Harrison conducts clinical testing of the device with Drs. Richard Meltzer and Jerry Griffin.

"Magnetocardiography may be helpful in diagnosing potential heart attacks which result from these conduction abnormalities," says Harrison. "It will complement but not replace the EKG.

"Many of the cellular properties related to the spread of impulses in the heart are not understood," he says. "The magnetocardiogram (MCG) will provide new insight into these properties."

The magnetic fields produced by the heart are very difficult to measure because they are one million times weaker than the earth's magnetic field, says Mark Leifer, graduate student in applied physics.

Leifer directs the development of magnetometry techniques with Prof. William Fairbank in the Department of Physics.

Previous efforts to pick up the tiny cardiac fields were hampered by magnetic interference, including power-line noise and even magnetic noise from cars driving along the street outside.

At Stanford this background noise was eliminated by placing the patient at the bottom of a 25-foot well lined with magnetic shielding.

The new SQUID magnetometer allows measurement at ground level without magnetic shielding, says Leifer.

Magnetocardiography is also being tested in Finland, France, and the Massachusetts Institute of Technology, says Leifer. Case Western Reserve University in Cleveland, Ohio, recently purchased a device for research.

So far the Stanford group is the only one which has "quantitatively demonstrated the accuracy of the measurement technique and ability of MCG to detect cardiac events not reflected in EKG," says Leifer.

In addition the Stanford researchers measure the magnetic field of the heart in three planes which are at right angles to each other.

This unique technique more accurately reflects events occurring in the heart, says Leifer, and can be used quickly and easily in a clinical setting.

The Stanford magnetometer was built by the S.H.E. Corporation of San Diego. Dr. John P. Wikswo, Jr., did much of the design when he was a graduate research associate in physics at Stanford. Wikswo presently is a member of the Department of Physics and Astronomy at Vanderbilt University in Nashville, Tennessee.

Stanford plans to conduct cooperative studies with Wikswo in the future, says Leifer.

The SQUID magnetometer in its present form can be adapted for hospital use, says Harrison. Because it is completely noninvasive and does not require the attachment of electrodes to the body like electrocardiography, it would make mass screening for cardiac problems easier, he said.

The device is expensive ($26,000) and requires the use of a computer. However, once it is manufactured on a mass scale the cost would be comparable to other diagnostic equipment, says Harrison.

STANFORD--Richard T. Johnson, professor of neurology and microbiology at The Johns Hopkins University School of Medicine, will present the second annual George A. Zimmermann Lecture at the Stanford School of Medicine on Wednesday, Feb. 22.

Dr. Johnson will discuss "The Possible Viral Etiology of Multiple Sclerosis" at 5 p.m. in Room M106 of the Medical School. The lecture is open to the medical community and the public.

Dr. Johnson, who holds the Dwight D. Eisenhower-United Cerebral Palsy Professorship at Hopkins, is an authority on the causes of viral infections of the nervous system, including those caused by rabies, myxovirus and herpes.

Dr. Johnson received his M. D. from the University of Colorado in 1956. Prior to joining the Department of Neurology at Johns Hopkins in 1969, he held positions in England and Australia, and was on the faculty of Harvard Medical School and Case Western Reserve University in Cleveland, Ohio.

The Zimmermann Lectureship was established in 1977 by the Department of Neurology at Stanford University School of Medicine. It is part of a $500,000 gift by the late George A. Zimmermann for multiple sclerosis research and treatment at Stanford.

A longtime San Francisco businessman, Zimmermann died in 1974. He bequeathed virtually all of his estate to various charities and for medical research.

STANFORD--Dr. Theodore Fainstat, a pioneer in gynecologic endocrinology, has been appointed professor of gynecology and obstetrics in the Stanford University School of Medicine.

His appointment, announced Tuesday, Feb. 14 by Dr. Clayton Rich, vice-president for medical affairs and dean of Medical School, will be effective March 1.

Dr. Fainstat has been visiting professor in the medical school, and director of obstetrics and gynecology at Santa Clara Valley Medical Center, since July 1977. He will continue to direct the program at Valley Medical Center, a Stanford-affiliated hospital.

Dr. Fainstat pioneered in developing the ovarian organ culture systems as a classic technique for studying ovulation and defining the factors that influence it.

He demonstrated that progesterone acts directly on the ovary to produce ovulation, rather than through the hypothalamus and pituitary gland as previously believed.

A native of Montreal, he obtained his M.D. from McGill University in 1955, and his Ph.D. from Cambridge University in 1970.

Before joining Stanford, he served as professor of gynecology and obstetrics at Kansas University Medical Center. He has also been associated with Northwestern University Medical Center, and Harvard Medical School and Boston City Hospital.

STANFORD--Licensed vocational nurses (LVNs) at Stanford University Hospital and Clinics have overwhelmingly rejected any union representation for purposes of collective bargaining.

In three days of voting conducted last week by the National Labor Relations Board (NLRB), 26 votes were cast. Twenty voted for "no union," while three voted for the California Licensed Vocational Nurses Association (CLVNA), and two for United Stanford Employees (USE). One vote was "challenged."

Two days before similar elections were to begin for about 1,200 service, technical and patient care employees and pharmacists, USE withdrew. These employees would have voted for USE as their exclusive bargaining representative, or for no union at all. USE is Local 680 of the Service Employees International Union, AFL-CIO.

The NLRB accepted USE's withdrawal "with prejudice," according to Gary A. Mecklenburg, administrator of Stanford Hospital and Clinics.

"This means that no petition for an election may be filed concerning the unit for at least six months," Mecklenburg wrote in a letter sent to hospital and clinics employees Monday, Feb. 6.

"USE must obtain newly signed authorization cards from at least 30 percent of the employees in the unit in order to file a petition with the NLRB for another election," Mecklenburg added.

Mecklenburg said the LVN vote represents an "affirmation of trust and confidence in our medical center" by employees.

At the time it withdrew from the major part of the elections, USE said in a newsletter that the elections were actually "postponed because of joint actions of Stanford and the NLRB."

However, the NLRB rejected USE contentions that Stanford had failed to provide the union with at least 30 days notice of the election, and that Stanford had failed to deliver the names of voters until Jan. 16, which USE said was three days late by NLRB rules.

EDITORS: Details follow asterisks.
FOR IMMEDIATE RELEASE

STANFORD—Seven young scientists at Stanford University Medical Center recently have been selected to receive funding by the Biomedical Research Support Grant for the year 1977-78.

The Grant is provided by the National Institutes of Health each year "to enhance the effectiveness and efficiency of biomedical and behavioral research" at medical institutions.

The Grant money is distributed by a faculty committee appointed by Dr. Clayton Rich, dean of the Medical School. Dr. Eric Shooter, professor of neurobiology, chairs the committee.

The grantees, all assistant professors, include Christos Constantinou, Ph.D. (urology), Raymond Hintz, M.D. (pediatrics), K. Alan Kelts, M.D., Ph.D. (neurology and pediatrics), Lawrence Mathers, Ph.D. (structural biology), Bryan Myers, M.B., Ch.B. (nephrology), Bruce Wallace, Ph.D. (neurobiology), and Douglas Wallace, Ph.D. (genetics).

* * * * * * *

Constantinou is studying the rate at which urine is propelled into the bladder by successive contractios of muscles which surround the kidney and ureter (peristalsis). The rate can be determined by recording with a microphone the sounds produced as the bladder fills.

Recently Constantinou was awarded the 1977 C.-E. Alken Price at the meeting of the German Society of Urology for his investigation of the pyeloureteral pacemaker system. The pacemaker initiates peristalsis in a manner similar to the stimulation of muscle contraction by pacemakers in the heart and stomach.

Hintz is attempting to isolate a protein which binds to somatomedin in the blood. Somatomedin is a circulating peptile hormone which is involved in the control of cell growth. Study of the binding protein may reveal how it effects the physiological actions of the hormone.

Kelts is studying the development of brain and nerve mechanisms which control the movements of the stomach and intestines in humans.

Mathers is studying how populations of nerve cells affect each other during growth in the chick embryo. In the chick there is a critical period during which the absence of a functioning eye results in degeneration and death of certain regions of the brain. This doesn't occur after hatching. Mathers is searching for a property or factor manufactured in the eye which is responsible for development of brain cells during this period.

Mathers is studying acute renal failure in patients who have had open heart surgery. He calculates the filtration rate of their kidneys by measuring excretion of inulin, a sugar, in the urine, and disappearance of the sugar from the blood. Inulin is excreted from the body only by filtration through the kidneys. This method may provide a means of monitoring postoperative patients, and detecting renal failure more quickly than conventional laboratory techniques.

Bruce Wallace is trying to determine how nerve cells accumulate neurotransmitters during development. Neurotransmitters are the chemical messengers which transport electrical signals across gaps, or synapses, between the cells.

Douglas Wallace is studying inherited disorders of mitochondria in humans, such as Luft's hypermetabolic syndrome. Mitochondria are tiny structures inside cells which provide the cell's source of energy. The mitochondria in patients with Luft's syndrome are defective, and cause muscle weakness, increased sensitivity to heat, and an enormous appetite. Related symptoms are found in other mitochondrial diseases. Wallace is trying to determine the genetic bases of these diseases and how the mitochondrial defect is expressed.

STANFORD--Dr. Jean-Pierre Changeux of the Pasteur Institute in Paris will present the fifth annual Windsor C. Cutting Memorial Lecture at Stanford University School of Medicine on Thursday, Feb. 9.

Dr. Changeux, a professor at the College de France, will discuss "Structure and Functional Properties of the Acetylcholine Receptor Protein" at 4:15 p.m. in the Fairchild Auditorium of the Medical School. The lecture is open to the medical community and public.

The Windsor Cutting Lectureship was established in 1973 by the faculty of the Department of Pharmacology and is supported by private contributions. It honors the memory of Dr. Cutting, professor and former chairman of the department. Dr. Cutting, who died in 1972, also served as dean of Stanford Medical School, 1953-57, and as dean of the University of Hawaii Medical School, 1963-71.

The lectures, which feature speakers prominent in the field of pharmacology, are given annually.

RELEASED IN CAMPUS REPORT, FEBRUARY 1, 1978

REPORT OF PUBLIC MEETING OF STANFORD ADMINISTRATIVE PANEL ON RECOMBINANT DNA MOLECULES ON FRIDAY, JANUARY 27, 1978

STANFORD -- Recombinant DNA research, the gene splicing experiments which aroused controversy during the last few years, continues at Stanford University under close public scrutiny.

Since September, 1976, an administrative panel on recombinant DNA molecules has reviewed all proposals and research activities which involve the transfer of genetic material between different organisms.

The 16-member panel, which includes University professors and staff, an expert in biosafety, and a public representative, ensures that such research complies with safety guidelines issued by the National Institutes of Health (NIH) in 1976.

The guidelines prohibit certain experiments which involve toxic substances and human cells. Other experiments are permitted, but only when specific safety precautions which correspond to their potential hazards are taken.

The panel is responsible for reporting any potential or apparent violation of these policies to University officials.

There are 19 Stanford scientists engaged in recombinant DNA research which is reviewed by the panel. Three of these scientists are also panel members; Paul Berg, Willson professor of biochemistry, Stanley Cohen, professor of medicine and genetics, and Ronald Davis, associate professor of biochemistry.

The panel meets about once a month. Every fourth meeting is open to the public. However, the minutes of every meeting are public record and are available at University libraries.

An open meeting last week at the Meyer Undergraduate Library at Stanford provided an example of how the review process works. About 20 people attended.

Most of the panel's business concerned review of research proposals. Berg outlined a proposal for growing recombinant DNA molecules from bacteria, yeast and fruit flies in mammalian cells.

"Ultimately, we'd like to be able to introduce specific animal genes into the chromosomes of mammalian cells and study how they are expressed," he said.

-more-

Berg said he intends to introduce new DNA into monkey or rodent cells by using the viruses, SV40 and polyoma, which naturally infect such animals.

The NIH guidelines require that viruses used to transfer new DNA into animal cells are made defective so they can not reproduce by themselves. In Berg's experiments, segments of the viral DNA necessary for reproduction are cut out and replaced with the new DNA.

A second precaution requires that the experiments are done under special laboratory conditions, designated P3, to prevent contamination outside the lab.

In addition, the new DNA must be purified so that no novel viruses containing unknown, toxic agents are produced. Purification is done by cloning, or growing the desired DNA segments in bacteria prior to combining them with viral genes.

"Do you have a P3 facility?" asked panel member Michael Arnush, an undergraduate student in anthropology.

"Yes," said Berg. "All experiments involving the growth of recombinant DNA in mammalian cells are done in this facility."

"How pure is the material you're putting into the viruses?" asked John Kaplan, professor of law.

The material to be combined with SV40 "is by definition homogeneous, as it has been purified by cloning," said Berg. All of the gene segments are identical. "Cloning is the most rigorous procedure for purification now available on this earth."

The requirements for purifying DNA which is then combined with polyoma are less stringent, he said, because, unlike SV40, the virus is not known to infect humans.

When the discussion had ended, Berg left the meeting room. A vote was called for, and the research was approved unanimously.

John Brauman, professor of chemistry, chairs the panel. Faculty staff members not involved in the research include Brauman, Kaplan, David Perkins, professor of biological sciences, Lucille Rasmussen, research associate in infectious diseases, Burton Richter, professor at the Stanford Linear Accelerator Center, Nathan Rosenberg, professor of economics, and Kenneth Vosti, professor of infectious diseases.

Panel members from outside Stanford are Mark Chatigny, chairperson of the University of California Biological/Environmental Department, Naval Biomedical Research Laboratory, Richmond, and Richard Rosenbaum, a former Palo Alto city councilman and research engineer at Lockheed.

Ex-officio members are John Bernard, occupational health and safety officer at the Medical Center, Patricia Devaney, assistant to the vice-provost for research, and Jack Sidlow, University manager of safety and health.

FOR IMMEDIATE RELEASE

STANFORD—

Dr. William Hayden, a radiologist who filed a law suit against Stanford University Hospital, will be recommended for appointment to the medical staff, according to the terms of an agreement ratified Tuesday, Jan. 31, by the Board of Hospital directors.

The agreement was reached by the Hospital and Hayden shortly before the Hospital board was scheduled to hold extensive hearings on the issues raised by the Hayden case.

Under the agreed settlement, Hayden will be granted certain clinical privileges subject to approval by the Credentials Committee and Medical Board of his professional competence.

Hayden will participate in the teaching of medical students, interns, residents, and fellows as requested by the Department of Radiology, and will cooperate in departmental research.

Hayden agreed to drop his suit against the Hospital now pending in Santa Clara County Superior Court.

Conrad Gullixson, president of the Board of Hospital directors, said he was pleased the dispute with Hayden was resolved.

At the same time, the Board issued a statement which said in part:

"The Board of Hospital Directors reaffirms its dedication to providing high quality care to all patients at a reasonable cost while maintaining strong educational and clinical research programs within the Hospital under the direction of the full-time faculty of the Medical School.

"The Board is particularly concerned with maintaining excellence in patient care, teaching, and clinical research within the Hospital-based clinical services where issues of quality control, coordination, standardization and cost efficiencies are critical.

"Because of this concern, during the next few months the board will examine carefully the operation of these Hospital-based clinical services where issues of quality control, coordination, standardization, and cost efficiencies are critical.

"Because of this concern, during the next few months the board will examine carefully the operation of these Hospital-based clinical services. This examination will include the desirability of maintaining closed staffs for such services and a review of all existing exceptions and special arrangements.

The Board said it will not accept applications for membership of privileges in Hospital-based clinical services while its review is under way. The Board intends to complete its review within the next four months. The Board also indicated that it will seek advice from various sources, including Hospital and medical school administration, and the medical staff.

According to Dr. Clayton Rich, dean of the School of Medicine and a member of the Hospital Board, "the radiology service of the Hospital has operated under a closed staff rule, but this rule has not been reviewed for many years. The Board wants to reassess the closed staff rules in all Hospital-based services, including pathology, anesthesiology, and radiology, but it has decided this must be done outside the context of an adversarial hearing."

The Hayden case emerged when the Palo Alto radiologist applied for membership on the medical staff of the Hospital and requested privileges in the division of diagnostic radiology.

While his original application was pending before the Hospital board, Hayden filed suit, contending that the hearing procedures would not afford him a fair hearing.

The Hospital had argued in court proceedings that the matter should be returned to the board for further hearings.

Last November, Santa Clara County Superior Court Judge J. Barton Phelps ruled that Hayden be granted a hearing before the Hospital Board.

STANFORD—

An exhibition of paintings, drawings and sculptures spanning 20 years by Dr. Joseph P. Kriss will be on display April 4-May 19 at the Syntex Gallery in Palo Alto.

Kriss, who is professor of medicine and radiology, and director of the Divison of Nuclear Medicine at Stanford University Medical School, has been painting for the past 30 years. His one-man show at Syntex, which is entitled 'Joseph Kriss: A Retrospective, 1957-77," is the first showing of his works since 1974.

Exhibits in Kriss's new show include oil paintings, single line pen drawings, and sculptures in cast resin and bronze using the lost wax process. The bronze pieces were completed in 1971 and the cast resins three years later.

A set of eight paintings in the show were completed in 1977 and are entitled the Cabo San Lucas Series. According to Kriss these paintings deal with "resolve, death, struggle, triumph, harmony and peace."

Kriss, whose first show was held in 1955 in San Francisco, has works in many private collections and in corporate offices in the San Francisco Bay Area, and in other parts of the country.

"I have not sought to achieve any special goal or style in my painting," Kriss says, "but the following considerations are dominant: I am a colorist, I am intrigued more by people and man-made objects than by natural scenery, I am aware of trying to create a mood in the paintings, and I want the viewer...to see new things with each new look."

Kriss, who has been on the Stanford Medical School faculty since 1948, was recently named one of eight Distinguished Alumni of Penn State University.

The Syntex Gallery is at 3401 Hillview Avenue in Palo Alto's Stanford Industrial Park. Hours are 10 a.m. to 4 p.m., Mondays through Fridays, and 1 to 4 p.m. Saturdays.

STANFORD—

Dr. Tag E. Mansour has been appointed the Donald E. Baxter Professor of Pharmacology at Stanford University School of Medicine.

His appointment to the endowed chair was announced by Dr. Clayton Rich, vice president for medical affairs and dean of the medical school.

Mansour, who is chairman of the Department of Pharmacology, is a widely recognized researcher, concentrating his investigations in the field of cell regulation and the effects of drugs on cellular control mechanisms.

A member of the Stanford faculty since 1961, Mansour was awarded an honorary doctor of science degree in 1974 by his alma mater, the University of Birmingham, England, for his work on enzymes that convert glucose to lactic acid within the cell.

Mansour received his bachelor of veterinary science, medicine and surgery degree from the College of Veterinary Medicine at the University of Cairo, Egypt. He studied physiology and pharmacology at Edinburgh University in Scotland, and in 1949 he earned a Ph.D. in pharmacology from the University of Birmingham, England.

In 1952-54 Mansour was a senior instructor and research associate in the Department of Pharmacology at Western Reserve University Medical School in Cleveland, Ohio, and during 1955-61 he was on the medical faculty in the Pharmacology Department at Louisiana State Medical School in New Orleans.

Mansour serves on the editorial boards of *Biochemical Pharmacology* and *Archives Internationales de Pharmacodynamie et de Therapie.* He is also consultant to the World Health Organization and the U.S. Public Health Service.

The Donald E. Baxter Professorship is named after the late physician, scientist and engineer who founded the Baxter Co. The company was acquired by the American Hospital Supply Corp. following Baxter's death.

The Baxter Foundation has also funded medical research and provided student financial aid at Stanford Medical School. In addition, it has helped fund construction and furnishing of diagnostic cardiology laboratories and related areas in Stanford University Hospital's new wing.

STANFORD—

The Stanford Arthritis Center is launching a long-term survey of persons with rheumatoid arthritis.

The researchers hope that 1,000 patients with rheumatoid arthritis throughout Santa Clara Valley will participate in the ten-year study which will provide vitally needed information about the course of this important disease.

The survey will be conducted by mail and by telephone and no physical examinations are involved. Patients will be asked a series of questions about how they are getting along with the arthritis, how much pain and stiffness they are having and how well they can do their daily activities. They will be contacted at approximately six month intervals during the study period.

The study does not provide treatment or advice. Survey assessors will not be able to answer questions about the disease and will refer the patient to his own doctor for such information.

The Stanford Arthritis Center, operating under a grant from the National Institutes of Health, was established under the National Arthritis Act of 1975.

Dr. Halsted Holman, professor of medicine at Stanford, is director of the Center and Dr. James Fries, associate professor of medicine, is associate director. Fries is director of the American Rheumatism Association Medical Information System, a nationwide data bank.

According to the investigators, they will examine both the medical costs of the disease and the social costs, such as interference with work activities. The role of different treatments in changing long term outcomes for patients will be evaluated.

Both patients and their physicians will receive reports of the survey at periodic intervals. No physician or patient names will be included in the reports of the study.

Persons with rheumatoid arthritis who wish to participate or learn more about the survey may call the Arthritis Center, (415) 497-5138. Local pharmacies also will be posting information about the study.

STANFORD—

Some of the least visible, yet important members of the Stanford University community are the postdoctoral scholars engaged in clinical and basic research.

"Postdocs" are individuals with an M.D., Ph.D. degree, or both, who are seeking further training in their specialty.

Postdoctoral scholars engaged in basic research carry out experiments and play a major role in the research programs of the faculty. Physicians who are receiving advanced training in a subspecialty may be actively involved both in clinical research and in patient-care.

Almost as large a group as the medical students, postdoctoral scholars in the School of Medicine number over 300. Unlike other students, 'postdocs" apply directly to the department and individual with whom they wish to work. Financial support is obtained from government sources such as the National Institutes of Health, private foundations and foreign governments. Length of stay at Stanford is about two years.

Approximately one out of every three postdoctoral scholars is from abroad. They come from more than 25 countries. Scholars from the United Kingdom, West Germany, France, Israel, Switzerland, Taiwan, Canada and Japan account for well over half of the fellows from abroad.

Britta Hardy, a postdoctoral fellow in the Division of Hematology, is from Israel. Born in Russia at the end of World War II, she and her family moved to Israel when Britta was three years old.

As a young girl, Hardy was fascinated by biology. "I have always been interested in understanding how the body functions—not only as one living unit, but as a complex machine composed of millions of single cells, each with their own unique role and molecular structure.

Dr. Hardy received a Ph.D. in cell biology from the Weizmann Institute of Science in 1975. She and her husband, Amos, a visiting scientist in the Department of Physics, came to Stanford University the following year.

Working in the laboratory of Dr. Stanley Schrier, professor of medicine, Hardy is studying one of the major proteins which make up the red blood cell membrane. Using immunobiochemical methods to purify and analyze the protein, Hardy hopes to determine if it is responsible for the shape changes that red blood cells undergo as they circulate through the body.

"When red cells cannot undergo these necessary shape changes, they are eliminated from the circulation," Hardy noted. "Diseases such as certain types of anemia may result from the premature death of these cells."

The Hardys and their two children, ages 8 and 5, live on campus in Escondido Village. A babysitter takes care of Einat when she comes home from school. Irit attends a day-care center.

The Hardys find their two-year stay in the United States a welcome change in pace from the highly charged atmosphere of daily life back in Israel.

"I am fascinated by the politeness of people in the streets...the nice manners," Hardy explained. "The atmosphere here does not have high tension. It has been a good time for both of us."

Tao-shih Hsieh, a young biochemist working in the laboratory of Dr. Douglas Brutlag, is from Taiwan.

At 22, Hsieh came to the United States to continue his studies. After receiving a Ph.D. in Chemistry from UC Berkeley in 1976, Hsieh entered Stanford as a postdoctoral scholar in the Department of Biochemistry.

(more)

Why did he choose Stanford? "The research environment in the Department of Biochemistry is one of the best in the country," Hsieh replied. "There is close contact and cooperation between the various groups."

Dr. Hsieh is studying the structure and function of heterochromatin of fruit flies. Heterochromatin is part of the cell nucleus and may be involved in the proper pairing of chromosomes in the reproductive cells, known as germ cell lines. Various genetic diseases are caused by improper pairing of chromosomes, Hsieh noted.

"Generally, the postdoctoral period is a very good, productive time for a scientist," Hsieh observed. "When I was a graduate student, I had to fulfill various requirements, as well as teach undergraduate courses. Now I have no other responsibilities and can concentrate on my research."

Dr. Hsieh's schedule is determined by the nature and schedule of his experiments. He works long and irregular hours—often until midnight. "I was married last year, however, and now I'm trying to work more regular hours," he added. Hsieh's wife, also a Berkeley graduate, works at Syntex.

Fiona Rubin, a physician from Glasgow, Scotland, is taking a postdoctoral fellowship in child psychiatry. She and her husband, Peter, a physician and postdoctoral scholar in clinical pharmacology, arrived at Stanford last summer.

As a practicing physician in the English Midlands, Rubin became aware of the lack of pediatric psychiatric facilities in Great Britain and "the crying need for people with a greater understanding of children's problems."

Working on the pediatric wards, she observed "the inability of pediatricians to deal adequately with the emotional turmoil of parents of sick children.

"Coping with the parents of a desperately ill newborn, of a child born with Down's syndrome, or some other severe disease, usually falls to the lot of the pediatric resident and calls for training that he has not had," Rubin noted. "Pediatricians need input on what to expect from parents' reactions and how best to handle them."

At Stanford, Dr. Rubin spends most of her time seeing patients ranging in age from early childhood to adolescence. She finds the program a great challenge. It has come as a major cultural shock, however, to Rubin that in the United States one must consider the patient's ability to pay for care when making recommendations for treatment.

"Issues regarding treatment are clearer when there are no financial considerations for patient or doctor," she believes.

The American way of life with its high level of affluence, loose lifestyles, and stress on individual self-fulfillment appears to be achieved at the expense of other values, Rubin observed.

Speaking slowly and searching for the correct words to describe her impressions, Rubin mused, "It is a strange kind of existence here for us. In the Midlands where we worked, we were an essential part of the hospital...of the community.

"Here, what we do does not appear to be as important...In Britain people go into medicine, perhaps for power, the idea of self-sacrifice, but certainly not for financial rewards. They expect demands to be made upon them and hard work, and, in return, there is the reward of a job well done."

The Rubins, who live in Escondido Village, have observed that Americans spend many more hours in organized activities and sports.

"At home, people tend to gravitate more to the homes of friends or to the hospital mess. Here, superficial contacts with American colleagues are easily made," she noted, "but, with a few major exceptions, they rarely progress beyond that.

"The British have a reputation for being cold and withdrawn, but, in fact, we've found that friendships are a much more important part of our lives."

A public information forum on the subject of sleep research will be held on Wednesday, April 5 in conjunction with the 18th annual meeting of the Association for the Psychophysiological Study of Sleep (APSS), sponsored by the Stanford Sleep Disorders Clinic and Research Center.

The information forum will begin at 9 a.m. at the Elks Club, 4249 El Camino Real, Palo Alto. APSS sessions will be held through April 9 at Rickeys Hyatt House, Palo Alto.

Several well-known sleep researchers are expected to participate in the information forum, including Dr. William C. Dement of Stanford; Dr. Daniel F. Kripke of the Department of Psychiatry at UC-San Diego School of Medicine; Dr. Elliot D. Weitzman of the Department of Neurology at Montefiore Medical Center, New York; Dr. Ismet Karacan, director of the Baylor College of Medicine Sleep Disorders Center, Houston, Texas; and Dr. Milton Kramer, director of the sleep laboratory at the Veterans Administration Hospital, Cincinnati, Ohio.

The panel will discuss public health aspects of sleep research, including the abuse of drugs used to induce sleep, insomnia, the diagnosis and treatment of sleep disorders, basic research directions, and the need for sleep disorder centers.

Other researchers, including Dr. Rosalind Cartwright of Chicago, well-known dream researcher, and Dr. J. Allan Hobson, director of the neurophysiology laboratory at Harvard Medical School, will also be available.

Note to Editors:

You are invited to attend the information forum and a press conference following.

A brief tour of the Stanford Sleep Disorders Clinic and Research Center is planned for the media following the press conference.

A press room will be available at Rickeys Hyatt House during the meetings.

STANFORD—

Plans for establishing an alternate birth center at Stanford University Hospital are being evaluated by hospital administrators.

In the meantime, "we're definitely going ahead with the design and decoration of two private rooms which can be used as necessary for alternate birthings," said Duane Walker, R.N., associate administrator of the hospital and director of nursing services.

The rooms are located in the postpartum unit in the hospital's west wing. Hopefully, they will be ready by mid-April, 1978, he said.

"The hospital's administration is receptive to the idea of an alternate birth center because of the need for one expressed by the community," said Walker.

Final plans will be drawn up in April, he said.

Stanford already offers several alternate birth procedures. These include allowing two persons in the delivery room with the consent of the obstetrician, allowing two persons in the labor room, and allowing labor and delivery in the same room.

After birth, the mother and baby can recover together in the same area where labor and delivery took place whenever possible.

Rooming in with the baby is allowed on the postpartum floor.

This year, the Hospital Medical Board approved three further procedures on a trial basis.

Husbands now can be present during caesarean deliveries except during an emergency.

Properly supervised children now can visit their mother during labor and after birth, they can visit their new brothers and sisters in the maternity unit.

Previously, childen under 16 years old could only visit outside the maternity unit in the solarium.,

The alternate birth center will centralize these procedures in a single location. Women who choose alternate birthing will be able to labor and deliver in a pleasant environment with their families around them.

Some of the procedures were implemented on the recommendations of the Hospital's Perinatal Care Committee, and the Birth Action Council, a group of parents in the community who have given birth at Stanford.

According to Dr. W. Leroy Heinrichs, chairperson of the Department of Gynecology and Obstetrics, "family bonding around the newborn is one of the most important considerations of the new practice...and sibling visits confirm that parent-child relationship at a time when the newborn may create anxiety for the other children in the family."

Dr. Errol C. Friedberg of Stanford University School of Medicine and Dr. Dale Oxender of the University of Michigan School of Medicine, who will take his sabbatical leave at Stanford, have been named Macy Faculty Scholars for 1978-79 by the Josiah Macy, Jr. Foundation.

Friedberg, an associate professor of pathology, will spend his sabbatical leave at the University of Goteborg Medical School in Sweden. He will study molecular mechanisms of repair of damaged DNA.

A 1961 graduate of Witwatersrand University School of Medicine in Johannesburg, South Africa, Friedberg came to the United States in 1965. Before joining the Stanford faculty in 1971, he was at The Walter Reed Army Institute of Research in Washington, D.C. and at Case Western Reserve University in Cleveland, Ohio.

Oxender, a professor of biological chemistry, will be in the Department of Biological Sciences at Stanford. His area of research is cell-free synthesis of membrane transport proteins from bacteria. He will arrive at Stanford in July.

Oxender received a doctorate in biochemistry from Purdue University. He has been a member of the faculty at Michigan since 1959.

The awards are made annually by the Josiah Macy, Jr. Foundation to support research of "outstanding faculty members of schools of medicine" on sabbatical leave.

Since the program's inception in 1972, the Foundation has made 155 awards totalling more than $3 million to faculty members from 56 institutions.

STANFORD—

Improvements in the use of bone cement have helped solve two major problems with hip joint replacement, according to three Stanford researchers whose work was recently honored by The Hip Society.

The major problems with the surgery are infection and loosening of the artificial joint from the bone, says Dr. David J. Schurman, assistant professor of surgery.

Both problems are related to a failure in the bone cement, the substance used to attach the artificial joints to the skeleton, he says.

Studies conducted by Schurman, Dr. Robert Piziali, associate professor of engineering, and Lyle Swenson, Jr., research associate in orthopedic surgery and mechanical engineering, suggest that infection can be effectively prevented by mixing the bone cement with antibiotic prior to applying it to the skeleton.

In addition, mechanical strength of the cement can be improved by ensuring that liquid, air or blood does not mix with the cement during application.

The researchers received the award for their work at the February 22, 1978 meeting of the American Academy of Orthopedic Surgery in Dallas, Texas.

The award, a $1,000 honorarium, was presented by The Hip Society "in recognition of preeminent excellence...of thermal, mechanical and antibiotic studies of bone cement relating to total hip replacement surgery."

Joint replacement surgery is one of the most common operations performed in the U.S. Over 100,000 total hip joint replacements and 30,000 total knee joint replacements are done in this country each year.

Most infections occur because the artifical joints do not have a natural blood supply.

Infections occurring near them are not readily fought by the body's immune system.

In Europe, an antibiotic called gentamicin is commonly added as a powder to the bone cement before the joint is put in place. The antibiotic leaches from the cement after it hardens and forms a protective barrier around the joint.

This procedure has not been approved in the U.S., but antibiotics can be given by injection or washed through the wound at the time of surgery, says Schurman.

The Stanford group tested the cement-antibiotic mixture in rabbits which had received knee joint replacements. When challenged by infectious agents, all of the rabbits were able to resist infection completely. Ninety percent of control rabbits, which did not receive antibiotic, developed infection after the challenge.

The antibiotic which leached from the bone cement did not reach toxic levels in the rabbits' blood. After a few days, it fell below clinical levels in the urine, says Schurman.

Mixing antibiotic in powder form with bone cement also did not affect the mechanical strength of the cement as shown in studies performed by mechanical engineering's design division.

"These studies suggest that mixing antibiotic with cement is a safe and effective means of protecting against infection," says Schurman.

Mechanical strength was affected, however, when liquid antibiotic, air, or blood from the bone mixed with the cement during the operation. "This causes very important decreases in strength," says Schurman.

The Stanford group also explored the theory that bone cement releases heat as it hardens and may kill bone tissue adjacent to it. Scar tissue which forms in the dead area may result in the cement loosening from the bone.

The researchers performed experiments with computers using clinical data from Stanford and other centers. These demonstrated that "bone cement is very safe and very unlikely to contribute to the thermal death of bone cells," says Schurman.

Therefore, heat factors probably do not contribute to loosening, he says.

The Stanford studies have been included in an application to the Federal Drug Administration to allow clinical trials of the antibiotic-bone mixture in patients undergoing joint replacement, says Schurman.

The research was supported in part by grants from the National Institutes of Health, the Orthopedic Research and Educational Foundation, and the Schering Corporation.

Mervin G. Morris, a department store chain executive, has been appointed by Stanford University Trustees to the Stanford Hospital Board of Directors.

Morris, a native Californian, is chairman of the board and chief executive officer of Mervyn's a chain of 42 department stores in California and Nevada. The Mervyn's chain is headquartered in Hayward.

Morris succeeds Mrs. O. Meredith Wilson, a member of the hospital board since 1970 who is moving from the area.

As a boy Morris worked in his father's department store in Delano before founding his own retail business in San Lorenzo in 1949. From that two-employee store he has built the Mervyn's chain which today employs more than 9,000 persons.

Morris is active in several national retailing organizations and is on the board of PG and E. In addition, he is a member of the board of the School of Business at the University of California in Berkeley, and an Associate at USC, and also on that school's Board of Councilors. He resides in Atherton.

STANFORD—

A new technique is being used to detect the toxic effects of an anti-cancer drug on the hearts of cancer patients at Stanford University Hospital.

The technique, called endomyocardial biopsy, originally was developed to monitor rejection of transplanted hearts.

It involves removal of tissue from inside the heart and examination under the microscope.

The biopsy is performed by inserting a catheter, with a clipper at the end into the patient's jugular vein and threading it down into the heart, where it snips off a small piece of tissue.

"We feel that the endomyocardial biopsy provides a useful means of monitoring toxicity of the anti-cancer drug adriamycin in the heart," said Dr. Margaret Billingham, assistant professor of pathology, at the 13th annual San Francisco Cancer Symposium March 3, 1978.

Billingham is conducting the research with Drs. John Daniels, assistant professor in oncology, Jay Mason, assistant professor in cardiology, and Michael Bristow, postdoctoral fellow.

The biopsy procedure is done with a wire device called a bioptome. The bioptome was developed at Stanford from a Japanese model by Dr. Philip Caves in 1973. Caves presently is head of the department of cardiovascular surgery at the University of Glasgow, Scotland.

The procedure is done under local anesthetic and the insertion is viewed through a fluoroscope. It can be repeated many times on an outpatient basis if necessary.

Over 1500 biopsies have been taken at Stanford hospital without one death, said Billingham. Two-thirds of them were done to monitor rejection in heart transplant recipients.

Billingham said the technique has also been used at Stanford in 75 cancer patients who have received adriamycin. The researchers are now seeking ways to prevent the effects of adriamycin on the heart.

Adriamycin is an antibiotic used to treat various forms of cancer. The drug kills fast-growing cancer cells by interrupting the manufacture of their genetic material.

In high doses, however, adriamycin also damages heart muscle cells and can lead to heart failure. Prior to the biopsy technique, detection of drug-related damage was made by changes in the EKG and clinical changes in heart function.

The biopsy can detect damage to cells before these other symptoms occur. In older patients, "the biopsy offers the only reliable method" of determining whether changes in heart function result from the effects of adriamycin or other conditions, such as coronary artery disease, said Billingham.

Biopsy studies in patients treated with radiation prior to adriamycin demonstrated that "previous radiation to the heart enhances the danger of toxicity from adriamycin," she said.

Adriamycin also produces a "recall" phenomenon in these patients, changes in their hearts similar to acute radiation damage even though the radiation was years prior to treatment.

Repeated biopsies can help physicians determine the dosage of adriamycin which is effective in fighting cancer, but which does not damage heart tissue, she said.

STANFORD—

Rev. Ernie Young knows what it means to face what he calls "ultimate questions." He has to help people do it all the time.

Young is chaplain at Stanford University Medical Center. His chaplaincy service helps patients deal with matters of life and death.

Young sees his job as religious "only in the broadest sense." The emphasis, he says, is on "faith—that life is a good gift and has meaning" rather than "belief in any particular relgious creed."

Young and his Catholic counterpart, Rev. John Hester, who also is a chaplain at Stanford Medical Center, counsel virtually thousands of patients each year.

Young says counselors simply reinforce faith and hope which are "immensely important to critical and terminal patients. The chaplaincy is available to simply care without ulterior motives. It is very tangible," Young says.

This kind of caring takes many forms—flying a man's daughter to be here with him before he dies, providing clothing for a patients soon to be discharged, arranging accomodations for families from out of town, or simply being with people when they need someone to care. Older people especially need this attention as their "support often dwindles in size," Young notes.

The chaplaincy office is directed by Young. He and Hester are assisted by secretary Louise Melle, who also provides occasional counseling to patients and family members.

The unique idea of a chaplaincy program in a nonreligious affiliated hospital, such as Stanford, was organized in 1974 by Young. Later that year he was joined by Hester, a Roman Catholic priest. The program involves close coordination wih community clergy as well.

Hester has developed a team of lay counselors to help him with the approximately 140 Catholic patients who are in the hospital daily. At least five of these lay counselors are skilled in counseling techniques, administer sacraments, and refer Hester to those patients who request him or who have special needs. Hester also spends considerable time in emergency, intensive care units, and the coronary care unit.

Young is responsible for patients of all other faiths. He has a ream of nine assistants, all skilled in counseling, and some of whom are working toward counseling degrees. Training courses are held for all volunteers.

Each day the chaplaincy is provided information on new patients. It then selects those patients who will be seen and decides which patients will be called upon first, Young explains.

Patients and their families are not the sole beneficiaries of the program. Young says he is pleased with the opportunity to combine clinical experience with teaching, and being able to bring this experience into the classroom. Courses dealing with biomedical ethics are offered to Stanford Medical School students, and in April a weekend course is planned dealing with emotions and death.

Medical students often accompany Young on his rounds to get a different insight into the patients and patient care. Young believes this experience has a profound effect on the students, and he notes that some students have made specialty choices based on relationships developed with patients in this manner.

The chaplaincy service will also provide its first clerkship for a medical student this year, Young said.

The chaplains also make an effort to be available to doctors and nurses to help deal with their ethical dilemmas and emotional drain. Support is provided to nursing staff on an in-service basis. For example, if a nursing unit is having a "low morale" period, the chaplains will discuss questions or issues which have brought the staffers to a low point.

Seminars are also offered through the chaplaincy for community clergy, and a chaplain's advisory committee meets monthly to make the service more effective, Young says. This continuing liaison with community clergy includes local clergy and physician representatives, medical faculty and staff.

The referral demand from physicians, nurses, and social workers is encouraging to Young. "It means that the kind of counseling and care provided by chaplaincy service is being recognized as an important part of the health care team."

Young's hope for the future is that patients will have their spiritual and emotional needs cared for, as well as their physical needs to ensure a "positive healing experience. We need to develop a holistic approach to health," he urged.

STANFORD —

Faced with an operating deficit of $700,000 for fiscal 1978-79, Stanford Medical School officials are taking steps to bring school expenses in line with revenues.

In a memo to departments, Dr. Clayton Rich, vice-president for medical affairs and dean of the school, said "it is necessary to make decisions now that will prevent an operating budget deficit increasing in future years."

Rich said his goal was to achieve savings "in a way least damaging to the academic programs."

The dean said he had asked department chairmen to identify additional methods of affecting savings, and advise about the extent to which some of his own suggestions might be implemented.

He said if measures to reduce the deficit are not taken, it would grow to $2 million in the next four years.

The budget gap has been caused by a combination of factors. They include sharp increases in operating costs and at the same time a decline in clinical income and overhead cost recovery on some research projects. An example of operating costs changes is an 85 percent hike in utilities next year.

Rich said he has set a budget ceiling of $18,250,000 for the school's operating budget, representing an increase of 8.6 percent over this year's budget. Operating budget includes administration and general expense, operations, maintenance, and salaries. It is a part of a total medical school and clinics budget totalling more than $63 million.

The proposed budget includes increasing faculty salaries 8 percent instead of 10 percent in 1978-79, reducing operating costs by $100,000 and reducing administrative costs 2 percent below projected levels in 1978-79, and maintaining a freeze in some faculty positions.

"In considering reduction of faculty positions," said Rich, "it is extremely important to be sure that it is done in a way that interferes least with the long-term academic strength of the school."

He said an analysis of each department and program is now under way to determine how best to accomplish this.

Rich said he had appointed a committee headed by Dr. Thomas A. Gonda to make recommendations about tuition. Among alternatives under consideration is a "one time increase" of $1000 for 1979-80 tuition beyond the university's annual tuition increase. This rise in tuition without additional financial aid considerations would increase the operating budget by $408,000 in 1979-80.

"We have set the tuition for medical students at 105 percent of the amount charged for undergraduate and graduate students elsewhere in the university," said Rich. "However, this amount is far below the actual costs of medical education and what a number of comparable schools now require."

He said he had asked the committee to advise him about the method of setting tuition for future years, and to what extent there should be provisions to help with student aid as part of such a revised policy.

Three-quarter tuition for regular undergraduate students in 1978-79 would jump from its present $4,695 to $5,130. For medical students it would be approximately $240 more per year.

FOR IMMEDIATE RELEASE

STANFORD—

Stanford University School of Medicine has received regular seven-year accreditation, according to Dr. Clayton Rich, vice-president for medical affairs and dean.

The Liaison Committee on Medical Education surveyed the medical school recently and has issued the results. "I am pleased to report that the survey team was very positive about almost all programs for the school," Rich said.

For the past five years Stanford medical school has had three- and two-year accreditations because of vacancies in key departmental chairmanships. Most of these have been filled.

Rich said a major problem still remaining and in which the committee expressed concern is the appointment of a department chairman in physiology, and the development of adequate facilities for this department. Efforts toward this end are under way.

The Liaison Committee is composed of members of the council on medical education of the American Medical Association and the execuive council of the Association of American Medical Colleges.

Accreditation of medical schools requires a proper balance between the number of students in each class, the resources of the institution, inlcuding faculty, facilities, and budget.

The survey team report commended the school for "an exceptionally strong emphasis in research, particularly on fundamental biomedical investigations carried on in the basic science and clinical departments."

It also noted the "high degree of interaction between the faculty of medicine and the faculty of the university as a whole, expressed as collaborative research and joint educational ventures."

The report said Stanford has highly individualized M.D. and Ph.D. programs, a large graduate medical training program (house staff and clinical postdoctoral fellows) with emphasis on subspecialty training.

These were appropriate objectives for the mission of the school, the survey team said, "and the objectives are being attained."

The report comments that the present organizational structure of the medical school, the hospital, and the university appeared appropriate.

"The medical school is looked upon by all components of the university as a major intellectual asset," the survey team commented. "It is also regarded as a professional school that is anomalously large, accounting for almost half of the total expenditures of the university, and employing about one-third of the university faculty.

(more)

"It has recognized differences from other schools in it goals, requirements and programs, and in its financial and administrative operations, it is largely decentralized.

"There is a firm assumption throughout the university, shared by the medical school, that the school should generate its own income and not require university unrestricted funds."

The survey team said the School of Medicine deserves commendation for the qualifications of its faculty. But it added, "If true that policies with regard to tenure impede the recruitment of faculty necessary for sound educational experience in affiliated hospitals, a review of these policies should be undertaken."

The report notes that, in spite of a period of inflation and recession, the School had made "remarkable progress" in expanding its physical plant. But clinical departments were still experiencing a shortage of space. These were surgery, cardiovascular surgery, anesthesiology, pediatrics, medicine, neurology, pathology, and radiology.

Additional facilities will be needed, the report urged. They are expansion of the hospital and supporting laboratory and ambulatory services, and a new science building to meet "critical long-range needs of physiology, microbiology, and other basic science and clinical departments."

The report found Stanford's admission procedures, counseling and evaluation of students "to be well done by capable and diligent members of the faculty."

Among favorable comments obtained by the survey team from students included:

. A lack of destructive competition among students, while preserving excellence, as measured by National Board scores and internship matching;

. a spirit of cooperation and minimal stress because of the pass-fail system;

. an elective curriculum which affords opportunities to pursue special interests in research or additional academic work;

. student participation in medical school committees;

. responsiveness of the Stanford medical school to needs of minorities;

. Stanford's ability to attract outstanding students.

The students, according to the survey team, listed several areas in which improvements were needed. These include a more centralized control of academic departments which tend to act as independent fiefdoms, elimination of course scheduling conflicts, monitoring of the quality of teaching in affiliated hospitals.

The administration was fully aware of these shortcomings and was seeking solutions, the surveyors said.

STANFORD—

Stanford researchers have found that memory can be improved by drugs which increase the transmission of a chemical messenger in the brain.

In a recent study to be published in *Science* magazine, "normal persons showed a significant improvement in their ability to learn new information after taking physostigmine," said Dr. Ken Davis of the Department of Psychiatry.

"We're now giving another drug, choline, to older people to see if it will reduce the loss of memory which often occurs during aging," he said.

The drugs, physostigmine and choline, increase the activity of nerve cells which contain acetylcholine. Acetylcholine is a chemical messenger which transmits electrical signals across gaps between nerve cells.

In the double-blind study, 19 subjects received a dose of physostigmine or saline, and then were given a list of 20 items orally to memorize. They wrote down what they could remember, and at the end of the trial were reminded of the items they missed. The test was repeated six times.

Persons who received physostigmine had significantly better recall than those who had gotten saline.

Those who performed the worst on the first trial, showed the most improvement after taking the drug, said Davis.

Physostigmine is a short-acting drug, remaining in the blood stream for one hour. However, it causes several side effects, including decreases in heart rate and arterial blood pressure, nausea and vomiting.

Because of the side effects, physostigmine is not being tested in older people.

Choline, a safer and longer-lasting drug, is being tested in these patients. Choline remains in the blood stream for six hours without causing side effects.

Preliminary trials in older people using choline so far have been unsuccessful in producing significant effects on their memory. Further work, using varying doses of the drug, is planned, said Davis.

The research is being conducted in the Clinical Research Center at the Palo Alto Veteran's Administration Hospital by members of the Department of Psychiatry including Dr. Davis, Leo Hollister, Bert Kopell, Richard Mohs, Philip Berger and Jared Tinklenberg.

"Autopsies of persons who suffered from senile dementia, a mental deterioration associated with old age, have shown that there is a loss of nerve cells which contain the chemical messenger acetylcholine," said Davis.

Drugs which reduce the activity of these nerve cells can produce a memory disorder identical with senile dementia, even in young people.

"These studies suggest that memory may be improved by increasing transmission in acetylcholine-containing nerve cells," said Davis.

STANFORD—

Sleep researchers from throughout the world will meet April 4-9 in Palo Alto to present their latest findings about topics such as the function of sleep, snoring, treatments for insomnia, and the role of sleep in children.

The press is invited to attend sessions of the 18th annual meeting of the Association for the Psychophysiological Study of Sleep (APSS), to be held at Rickey's Hyatt House under the direction of the Stanford Sleep Research Center.

A Public Information Forum, followed by a press conference, is scheduled for Wednesday, April 5. A panel of well-known sleep researchers, including Dr. William C. Dement of Stanford, will conduct an educational session on the public health aspects of sleep research, such as the abuse of aspirin and other drugs used to induce sleep, and apnea or episodes of stopped breathing during sleep.

Workshops during the week will focus on issues such as sudden infant death syndrome, narcolepsy, and other sleep disorders.

New research is expected to be presented about the association of sleep apnea to hypertension, whether certain patterns of snoring may predict obstructive sleep apnea, and whether a child's need for sleep changes with age.

One workshop is planned on the chemistry of sleep. It includes polypeptides and sleep, relating new knowledge on encephalins and endorphins and consideration of a sleep polypeptide.

Among the 200 researchers expected to attend are Rosalind Cartwright, well-known for her work on dreams, and Elliot Weitzman of the Sleep-Wake Disorders Unit at Montefiore Hospital, New York.

More than 65 presentations will be on exhibit at a "science fair," located at Rickey's. Also planned is a "film festival," entertaining movies on sleep, plus the showing of a new film on narcolepsy.

Concurrent with the meetings will be the San Francisco Exploratorium exhibit "Dreamstage." Visitors to that exhibit, located at the Palace of Fine Arts, will view a sleeping human subject, selected by Stanford's Sleep Disorders Center, whose brain, eye and muscular movements will be translated into color, sound, and music. In the learning center portion of the exhibit, sleep experts will be on hand to answer questions.

The News Bureau will handle press arrangements during the APSS meetings. A detailed program and abstracts will be available soon. If you plan to cover, please return the form attached.

FOR IMMEDIATE RELEASE

STANFORD—

Approval to license development of a recombinant DNA research technique has been granted to Stanford University by the National Institutes of Health (NIH).

Dr. Donald S. Fredrickson, NIH director, said in a March 2, 1978, letter to Robert Rosenzweig, Stanford vice-president for public affairs, that development of the technique can continue if the licensee complies "with the physical and biological containment standards set forth in the NIH guidelines."

The guidelines, established in 1976, ban hazardous experiments and allow others under strict containment procedures. They presently apply to federally funded research only.

According to Rosenzweig, the University is investigating the licensing question and has made no decisions. "We don't want to do anything that would interfere with legislation relating to recombinant DNA research now before Congress," he said.

The legislation would require that the guidelines also apply to private researchers, including industry.

The technique was developed by groups headed by Dr. Stanley Cohen, professor of medicine and genetics at Stanford University School of Medicine, and Dr. Herbert Boyer of the University of California-San Francisco. They published their findings in 1973 and 1974.

The technique involves transplanting genes from higher organisms into the bacterium *E. coli* by means of a plasmid carrier. Plasmids are small DNA segments carried by and sometimes transferred between bacteria.

Scientists hope to use the technique to introduce genes into easy-to-grow bacterial cells, converting the bacteria into factories of biological substances such as insulin and hormones.

The research by Cohen and Boyer was funded by the NIH, the American Cancer Society, and the National Science Foundation. These agencies agreed the technique should be administered under an institutional patent agreement between Stanford and the NIH.

The agreement allows the University to grant licenses for continued development of the technique, and gives it sole patent rights.

A patent application has been filed by Stanford and UC, and is now being considered by the U.S. Patent Office, according to Niels Reimers, manager of Stanford's technology licensing program.

"We have the right to patent and license this technique under our agreement with the NIH," says Rosenzweig. "But because of the controversial nature of recombinant DNA research, we asked for specific approval from the NIH before taking any further action."

In this letter to Rosenzweig, Fredrickson confirmed Stanford's rights to license and patent the technique, but only on the condition that companies which develop it under the license adhere to the NIH guidelines.

Under these conditions, licensing would benefit the public interest by requiring adherance to the guidelines within industry.

However, Fredrickson said "use of the institutional patent agreement as a means of obtaining compliance with the NIH guidelines is not an adequate substitute for legislation.

"If legislation is passed, these safety standards will be mandated by the law for all who conduct or support recombinant DNA research."

FOR IMMEDIATE RELEASE

STANFORD --

Dr. Victor W. Sidel, an internationally-recognized authority on health care delivery systems, will present two free public lectures Wednesday, March 15 at Stanford Medical School.

Sidel will speak on "Medical Care and Medical Education in Cuba: New forms of Socialized Medicine" at noon in Room M-104, and "Medicine in China Revisited, 1971-77" at 8 p.m. in Fairchild Auditorium.

Sidel is professor and chairman of the Department of Social Medicine at Montefiore Hospital and Medical Center, and at Albert Einstein College of Medicine in the Bronx.

He has served as instructor in biophysics at Harvard, consulting physician in medicine for the Family Health Care Program at Boston Children's Hospital, and head of Community Medicine at Massachusetts General Hospital in Boston.

Currently, Sidel is concentrating his teaching and research in community health, particularly in the Bronx.

Sidel has studied health care in many foreign countries, including China. His book Serve the People: Observations on Medicine in the People's Republic of China was written with his wife Ruth. Sidel's latest book A Healthy State: An International Perspective on the Crisis in U.S. Medical Care compares medical care in the U.S. with that in sweden, England, Russia and China.

Last year Sidel served as a consultant on health services research to the World Health Organization in Geneva, Switzerland. Among his many world trips was one to China in 1977, his third as a guest of the Chinese Medical Association in the past six years. Earlier this year he visited Cuba at the invitation of the Cuban Ministry of Health.

Sidel received his A.B. (cum laude) from Princeton and his M.D. from Harvard in 1957.

FOR IMMEDIATE RELEASE

STANFORD—

Changes in the pressure of fluid surrounding the brain can now be monitored continuously and noninvasively in humans with a device developed by Stanford physicians and engineers with the National Aeronautics and Space Administration (NASA).

Increases in intracranial, or brain fluid pressure which result from head injuries, tumors, surgery, or fevers can damage the brain and may be fatal.

Early detection and treatment of these pressure rises may prevent brain damage and increase the patient's chance of recovery.

The device, called an intracranial pressure monitor, converts pressure signals into radio waves and relays them to a receiver. The transmission of physiological signals in the form of radio waves is known as biotelemetry.

The first implant of this device in a patient on the West Coast was performed Feb. 16, 1978 by Dr. Gerald Silverberg, assistant professor of surgery at Stanford University Medical Center.

"This is one of the few workable telemetry devices which is accurate and stable," said Silverberg.

The patient was a young man who required surgery to remove a brain cyst. Sivlerberg said he implanted the monitor because of the risk of the brain swelling and increased fluid around the brain as a result of the surgery.

The pressure values obtained by the device were checked against spinal fluid pressure readings. "The values matched extremely well," said Silverberg.

"The surgery worked out beautifully," he said, "and the pressure in the brain did not increase."

The device was removed from the patient after five days. It will be recalibrated, sterilized, and used again in patients who have a high risk of increased intracranial pressure.

In the past, pressure has been measured by inserting a catheter into the brain, a technique that is difficult and can be risky.

The intracranial pressure monitor, on the other hand, provides a safer way of measuring pressure changes without puncturing the membrane which surrounds the brain.

The thimble-sized device is fitted through a 16 millimeter hole drilled in the skull so that it touches the brain membrane but does not pierce it. The device is then covered by the scalp.

Radio signals sent by the device are picked up by an external coil placed above the scalp. After processing by a computer, the signals are displayed on a chart in graphic form.

(more)

The device is externally powered by radio frequency waves, eliminating the need for wire connections or batteries.

Arterial blood pressure, blood gases, and heart rate, which are related to intracranial pressure values, are monitored separately.

The intracranial pressure monitor was developed by Thomas fryer, a NASA engineer at the Ames Research Center in Mountain View. Part of the device consists of a transducer used in advanced aircraft and space flight experiments at Ames.

NASA engineers and Stanford physicians have been cooperating in the development of the device as part of the Stanford Biomedical Application Team (BATeam).

The Stanford BATeam is one of four established by NASA in 1966 specifically to transfer aerospace technology to the solution of biomedical problems.

Dr. Donald Harrison, Dr. Eugene Schmidt, and Harry Miller of the division of cardiology direct the BATeam.

Three monitors built by Konigsberg Instruments, Inc., of Pasadena, California, "have performed adequately in long-term bench and animal tests," said Dr. Schmidt," and are approved by the Human Subjects Committee for use in patients."

Drs. Silverberg, Steve Corbin, biomedical engineer, and Allen Ream, assistant professor of anesthesia, are conducting clinical evaluation of the device.

According to Schmidt, the BATeam has contracted with a Southern California company to produce additional monitors.

The present devices are expensive (about $3,000 each) and require processing of the monitor signal to obain pressure readings.

Eventually, said Schmidt, a cheaper, more simplified device will be developed which can be used in any hospital.

The present devices are not designed for permanent implantation. However, it is possible to house the transmitter in a titanium alloy, for instance, which can be left in the body for many years, said Schmidt. Titanium is an inert metal frequently used in heart pacemakers. It is not rejected by the body.

Permanent implantation would permit long-term monitoring in patients with conditions such as hydrocephalus, abnormal buildup of fluid in the brain, said Schmidt.

FOR IMMEDIATE RELEASE

STANFORD—

Premature ventricular beats (PVBs) in patients with heart disease "are harbingers of sudden death," and should be treated with drug therapy, according to Dr. Donald C. Harrison, head of the division of cardiology at Stanford University Medical Center.

PVBs are a form of abnormal heart rhythm characterized by contractions of the ventricles prior to the normal beat.

Harrison, holder of the endowed William G. Irwin professorship of medicine in the School of Medicine, adressed the 27th annual meeting of the American College of Cardiology in Anaheim Tuesday, March 7. The meeting highlighted current controversies in cardiology.

Over 600,000 people die of heart disease in the U.S. each year, many from acute heart attacks. About 60% of deaths from heart attacks occur suddenly, within an hour after symptoms begin and before the victim can reach a hospital.

In many cases death results from a failure of electrical conduction in the heart. Heart muscle cells, which usually contract in unison, begin to beat independently, and prevent the heart from pumping efficiently. This is called fibrillation. The heart in this state has been described as "a can of worms."

Evidence from published studies demonstrating the link between frequent or complex PVBs and sudden death in patients with heart disease is"overwhelming at this time," said Harrison.

Antiarrhythmic drugs which control abnormal heart rhythms should be given to these patients and "perhaps to all patients who are recovering from acute heart attacks," he said.

Harrison cited studies in Britain and Sweden which showed a reduction in deaths among heart patients who received the drugs.

Antiarrhythmic therapy should continue for up to a year after the heart attack, he said.

Heart attacks kill about 10% of patients who have had previous attacks or abnormal rhythms within a year after leaving the hospital, according to a study conducted by Harrison, Dr. John Schroeder, and Irene Lamb, R.N., of the division of cardiology.

"We must concentrate on reducing deaths which occur outside the hospital," said Harrison. Monitoring patients during exercise can help define those with heart disease and abnormal rhythms who are susceptible to sudden death, he said, and for whom drug treatment will be beneficial.

STANFORD—

Among the most widely cited authors of scientific papers--"citation super-stars"--are four scientists at Stanford University, according to a recent survey.

Carl Djerassi, professor of chemistry; Nobel laureates Paul J. Flory, professor emeritus of chemistry, and Arthur Kornberg, professor of biochemistry; and Seymour Levine, professor of psychology in psychiatry and behavioral sciences,are listed among the 250 most-cited primary authors, based on a survey of the *Science Citation Index* 1961-75.

Assuming that over one million scientists worldwide have published during this period,these 250 authors account for less than one percent, according to Eugene Garfield of the Institute for Scientific Information.

Authors of scientific papers acknowledge prior work by citing it in their own papers. These acknowledgements are regularly compiled in the *Science Citation Index,* Garfield noted.

"The number of citations is positively correlated with the scientific value of the cited work," he believes. "Papers which receive a large number of citations are usually found to have reported significant new scientific knowledge. And the most-cited authors are likely to be scientists who have had significant impact on the development of science."

Every author included on the list has been cited more than 4,000 times, or a yearly average of at least 266. Since the average cited author receives about 8 citations per year, each of these 250 authors is clearly a "citation super-star," according to Garfield.

Djerassi is the principal developer of oral contraceptives. Flory won the 1974 Nobel prize in chemistry for his pioneering research on polymers. Kornberg received the Nobel prize for his discovery of the mechanisms involved in biologic synthesis of DNA. Levine's research is in the areas of physiological and behavioral development, including stress, hormones and varieties of infantile experience, as they affect behavior.

Because older scientists have been publishing, and therefore accumulating citations longer than younger ones, the average age of the most-cited authors was 63 and none were younger than 40.

The list of most-cited authors was based only on primary author data--that is, a citation to a paper with three authors would be credited only to the first author, Garfield said. Because of the growing number of multi-author papers, future citations will be credited to all co-authors of a given publication, and a whole new data base will be assembled, he said.

Heart transplant pioneer Dr. Norman E. Shumway will present the second in a series of public lectures on the heart on Wednesday, May 3, at 7:30 p.m. in the Sherman Fairchild Auditorium.

Shumway's topic will be "Heart Surgery: Accomplishment and Prospect." He will discuss current cardiovascular surgery, including coronary bypass, valve replacement, and transplants, and the possibilities of further advances.

Shumway holds the endowed Frances and Charles Field Professorship and is chairman of the Department of Cardiovascular Surgery at Stanford. Aside from his well-known work with cardiac transplantation, Shumway's major accomplishments have been in the field of open heart surgery, particularly in the transplantation of valves.

The lecture is open to the public, and there is no admission fee.

The Progress in Medicine Lectures are presented as a community service by the dean and faculty of the School of Medicine and by members of the Medical Center Council.

Future programs will be held on May 10, " After the Heart Attack: Rehabilitation," by Dr. Robert F. De Busk, and on May 17, "Heart Disease Prevention: A Way of Life," by Dr. John W. Farquhar.

Dr. Philip Schein, professor of medicine at Georgetown University, will present the second Frederick Hurd Welland Memorial Lecture at 4:45 p.m. Tuesday, May 2, in the Fairchild Auditorium of Stanford University School of Medicine.

Schein, chief of the division of medical oncology at Georgetown and the Vincent Lombardi Cancer Center in Washington, D.C., will discuss "Therapeutic Management of Gastrointestinal Cancer." Members of the medical community and the public are invited to attend.

Schein formerly headed the clinical pharmacology section at the National Cancer Institute, and is a leader in the field of endocrine tumors, gastrointestinal cancer and new drug development.

A graduate of Upstate New York Medical School, he received advanced training and held positions at Harvard Medical School, the National Cancer Institute and Oxford University.

Schein is at Stanford as a visiting professor sponsored by the Northern California Cancer Program.

Dr. Welland, a Palo Alto physician who had been chief resident in medicine and a fellow in oncology at Stanford, died in 1973. The lectureship was established in his memory by family and friends.

STANFORD—

Up to 18 percent of all poverty may be caused by disability, says a Stanford researcher.

Overall at least 30 percent of all poor families with a disabled adult are poor because of the disability. In families with a disabled white man, the proportion who are poor because of disability rises to 75 percent.

These are among the findings described by Harold S. Luft, assistant professor of health economics at Stanford, in his new book, *Poverty and Health: Economic Causes and Consequences of Health Problems* (Ballinger Publishing Co., Cambridge, Massachusetts, 1978, 157 pp.)

According to Luft, disabled people with less education, those initially in low paying jobs, blacks, and women are more likely to be adversely affected by a health problem and suffer greater reductions in job earnings.

Luft's studies are based on data from the 1967 Survey of Economic Opportunity and the 1966 Survey of Disabled Adults, conducted for the Social Security Administration.

The national sample included about 30,000 households, which were asked whether there was a disabled adult in the home. Disability was defined as "a limitation in the kind or amount of work resulting from a chronic health condition or impairment lasting three or more months."

Using these data, Luft examined disability for various categories of people by race, age, and income. He also estimated earnings losses for different groups.

"There is substantial evidence that the incidence of health problems is not random and that, in fact, the poor and less well-educated do have higher rates of disabling conditions," says Luft.

He found that income and disability rates are related. A poor person is at least twice as vulnerable to being afflicted with a chronic health problem than one in the $8,000 and over income class.

The probability of an on-the-job disability, even when controlled for a number of job characteristics, is greater for those with less schooling.

Thus, the average man with 10.5 years of school would have twice the risk of disability if he had only 5.5 years of formal education.

Luft's figures show that about 17 percent of the U.S. population between the ages of 18 and 64 have some disability. He estimates that $22 billion, or about 6 percent of all wage and salary earnings in the U.S., were lost by disabled persons in 1967.

"The magnitude of the problem is large and growing," he says. "A seventh of the working age population is disabled. While more can and should be done to offset income losses, the primary focus...is to prevent health problems and to reduce their severity."

Luft feels that a new system of disability compensation should replace the fragmented systems in use now. He calls for vocational rehabilitation that focuses on those who need it most.

A system that places responsibility for disability compensation at the local or regional level, rather than with the federal government, would be more effective and have consumer involvement, he says.

A region, he says, should be of a size where problems can be more readily identified and changes made.

"A region should be sensitive to its own disability and medical care budget, so it can start to promote, for example, a jogging program, nutrition classes, or environmental protection, or organize in other ways to make changes they see as necesary," says Luft.

This should not be just more rehabilitation and wage subsidies, he says, but rather a comprehensive system, with incentives and feedback mechanisms.

STANFORD—

The first successful treatment of chronic active hepatitis B infection with a synthetic antiviral drug has been reported by Stanford University Medical School researchers.

Treatment with vidarabine (adenine arabinoside) led to a significant decrease in the virus particle markers for hepatitis B infection in two patients, they reported.

Vidarabine, which inhibites replication of certain DNA viruses in tissue culture, previously has been shown to significantly reduce mortality in herpes simplex encephalitis patients. It is licensed for local use in herpes simplex infection of the eye.

A report of the hepatitis study appears in the April 21 issue of the *Journal of the American Medical Association*. Authors are Drs. Richard B. Pollard, Joseph L. Smith, Thomas C. Merigan and William S. Robinson of the division of infectious diseases, and Drs. Peter B. Gregory and F. Andrew Neal of the division of gastroenterology.

According to Pollard, 10 additional patients have been treated with vidarabine, including several with a combination of vidarabine and interferon, and antiviral agent normally formed in the body in response to viral infection.

The Stanford group first reported the effect of interferon on chronic hepatitis B infection in 1976.

Some patients, however, may not respond completely to interferon treatment, says Pollard. Better responses may be expected for some patients, he says, if current studies indicate that combined treatment is effective.

Physicians with patients having chronic hepatitis B infection who wish them to participate in therapy trials during the coming months are encouraged to contact the Stanford division of infectious diseases.

Hepatitis B virus cannot be grown in tissue culture, says Pollard. Experimental antiviral agents must therefore be clinically tested in patients.

Hepatitis B virus causes inflammation of the liver. About 10 percent of those who develop the acute infection continue to carry the virus in their liver and blood. It has been estimated that 175 million persons in the world today are chronically infected with the virus and therefore are potential transmitters of the infection.

Spontaneous recovery is rare. Eradication or control of the infection appears to depend on the development of antiviral drugs, say the researchers.

They say further investigations are necesary to determine how regular and permanent the effects of vidarabine will be.

Because the drug produced side effects in their study patients, they caution that its use in patients with more severe or acute infection should be avoided until further studies are completed. Side effects include transient nausea, weight loss, constipation and abdominal cramping.

The Stanford group is supported in this work by the Antiviral Substances Program of the National Institute of Allergy and Infectious Diseases.

Dr. Rodney Porter, Nobel laureate and pioneer in the field of antibody structure and function, will speak on complement fixation at the Stanford University Medical Center, Room M104, Monday, April 24 at 12 p.m.

Porter, head of the biochemistry department, Oxford University, England, shares the 1972 Nobel prize in medicine with Dr. Gerald Edelman for working out the structure of the antibody molecule.

Antibodies are protein molecules involved in the body's immune responses against foreign agents, such as bacteria and viruses. These molecules combine with, or fit, their target agent in specific ways, just as a round peg fits only a round hole.

The binding of antibody to agent sets off a chain of reactions involving other serum proteins, called complement. This causes the foreign agent to dissolve.

Porter has worked out the mechanism of initiation of the complement-aided reaction.

The lecture is sponsored by the Division of Immunology and is open to the public.

STANFORD—

Two years after receiving a heart transplant at Stanford University Hospital, Louis Bonesio could barely walk. His heart was fine, but he had developed an arthritic condition in his hips so severe that he was in constant pain.

Bonesio suffered from a side effect of one of the drugs he was taking to prevent rejection of the foreign heart tissue by his body.

Prednisone, a drug used to suppress the body's immune responses, is associated in some patients with progressive deterioration of their joints.

The relationship between the drug and joint disease is not completely understood. It is not known how frequently this condition occurs in heart transplant patients, but it has also been observed in patients with transplanted kidneys.

The only alternative to a wheel chair for Bonesio was total hip joint replacement.

Joint replacement surgery is one of the most common operations performed in the U.S. Over 100,000 total hip joint replacements are done in this country each year.

Since 1971, nearly 450 total hips have been replaced at Stanford's Hip Clinic. The Hip Clinic is directed by Dr. David S. Burton, associate professor of clinical surgery. Joint replacements also are performed at the Surgical Arthritis Clinic, directed by Dr. David J. Schurman, assistant professor.

Over ninety percent of the operations are successful, says Burton, but patients with transplanted hearts are at greater risks from the surgery.

The immunity suppressing drugs they are taking make them more susceptible to infections than other patients. Transplanted hearts are without nerves and may respond poorly to anesthesia.

However, "with proper management and careful monitoring, the risk of anesthesia can be reduced to reasonable levels," says Burton.

Bonesio decided to take the risks. In two successive operations, Burton replaced the worn-out and dying bone of Bonesio's hips with new stainless steel and plastic joints. Bone cement was used to attach the artificial joints to the skeleton.

After each operation, Bonesio spent one day in the intensive care unit where his heart was carefully monitored. Then he was moved to a regular hospital ward, given antibiotics, and "treated just like any other patient," says Burton.

The second day after the last operation, Bonesio was on his feet. Within a week he was walking with just a cane to support him. Today, over eight months later, he is without pain and has essentially full range of motion in both hips.

The results of total hip joint replacement in two other transplant patients were reported in the January-February 1978 issue of *Clinical Orthopaedics and Related Research* by Burton and Drs. Robert M. Mochizuki and Alan A. Halpern.

Both patients have responded well to surgery, and have full use of their hips one year and two years after their operations.

Burton and his colleagues are now studying how prednisone may cause hip joint degeneration, and with what frequency it occurs in heart transplant patients.

Bonesio is not letting a transplanted heart and artificial hips deter him from enjoying life. Retired from a family winery, his leisure pursuits include backpacking and hot air-ballooning. "My goal is to be around for a long time," he says. "I want to be the world's oldest living cardiac transplant."

Noted Stanford cardiac physicians and researchers, including transplant pioneer Dr. Norman E. Shumway, will present a new series of public lectures on the heart, the accomplishments of heart surgery, and heart disease prevention and rehabilitation.

The Medical Center's Progress in Medicine Lectures will begin Wednesday, April 26, at 7:30 p.m. in the Sherman Fairchild Auditorium, and will be held at the same time on the three succeeding Wednesday evenings.

The public is invited, and there is no admission fee.

Dr. Roger A. Winkle, assistant professor of medicine (cardiology), will present the first program, "The Heart: Anatomy and Function." He will discuss how disease affects heart functions and how heart disease is diagnosed.

Winkle has been involved in the treatment of patients with cardiac arrhythmias and the evaluation of new drugs to treat arrhythmia. He received his M.D. degree from the University of Cincinnati, and has been at Stanford since 1973.

Dr. Shumway will deliver the second lecture, May 3, on "Heart Surgery: Accomplishment and Prospect." He will provide a look at current cardiovascular surgery, including coronary bypass, valve replacement, and transplants, and the possibilities of further advances.

Shumway holds the endowed Frances and Charles Field Professorship and is chairman of cardiovascular surgery at Stanford. Aside from his well-known work on cardiac transplantation, Shumway's major accomplishments have been in the field of open heart surgery, particularly in the transplantation of valves.

He also developed techniques for total surgical correction of "blue baby" heart defects.

Future programs will feature:

On May 10: "After the Heart Attack: Rehabilitation," by Dr. Robert F. De Busk, assistant professor of medicine (cardiology). De Busk is director of Stanford's comprehensive cardiac rehabilitation program, and will discuss present techniques to facilitate a heart patient's return to normal activities. The rehabilitation program uses exercise testing and training, physical therapy, psychological and dietary counseling.

On May 17: "Heart Disease Prevention: A Way of Life," by Dr. John W. Farquhar, professor of medicine. Farquhar will discuss high risk factors in heart disease, and effective ways to control them.

Director of the Stanford Heart Disease Prevention Program, Farquhar developed the Three Communities Study in northern California, in which a mass media campaign aimed at lowering residents' risks of heart disease.

The Progress in Medicine Lectures are presented as a community service by the dean and faculty of the School of Medicine and by the members of the Medical Center Council.

The third annual Joe DiMaggio-Executive Pro-Am Golf Tournament will be played Friday, May 5, at the Half Moon Bay Golf Links.

Proceeds from the event will be donated to the Department of Dermatology at Stanford University Medical School for psoriasis research.

Tournament coordinator Rich Fancher estimates that about 180 golfers will enter. Entry fee is $175 and over $10,000 in prizes will be presented to the winners. In addition, a 1978 Cadillac Seville, donated by a Menlo Park auto dealer, will be awarded to any golfer hitting a hole-in-one at the 13th hole.

Entertainer Tennessee Ernie Ford will serve as master of ceremonies at the awards banquet to be held the night of the tournment. Also at the event, DiMaggio will present a tournament proceeds check to Dr. Eugene Farber, chairman of the Dermatology Department at Stanford.

The Half Moon Bay Golf Links at Ocean Colony is located about 28 miles south of San Francisco on U.S. Hwy. 1. The 7,105 yard course opened in 1973 and is considered among the most difficult in California.

The tournament honors DiMaggio, a former baseball great with the New York Yankees and a member of professional baseball's Hall of Fame. DiMaggio has received many honors and awards over the years and in 1969 he was named baseball's greatest living player by sportswriters and fans.

Additional tournament information may be obtained from the Half Moon Bay Golf Links at (415) 726-4438.

Classical homeopathy will be the subject of a free public lecture at Stanford University School of Medicine's Fairchild Auditorium April 27, 1978 at 7:30 p.m.

Homeopathy is a highly controversial approach to the treatment of diseases. People with certain diseases are treated with specially prepared doses of plant, mineral or animal substances which produce symptoms of the same diseases in healthy people. Its philosophy of "like cures like" dates back to the time of Hippocrates.

The lecture will be given by George Vithoulkas, director of the School of Homeopathic Medicine in Athens, Greece, and by Dr. William Gray, Mill Valley physician, nutritionist and homeopath. Gray is a Stanford medical school alumnus.

The lecture is sponsored by the Stanford Medical Students Association, the Bay Area Homeopathic Association and New College of California.

Vithoulkas will also deliver a series of lectures on the philosophy and methodology of homeopathy April 29-May 1 at New College in San Francisco. Continuing education credit is available for physicians and nurses. Persons interested in the lecture series should call (415) 383-5343.

STANFORD

Two rooms at Stanford University Hospital have been redecorated and remodeled for future use as an alternative birth center.

Women who choose alternative birthing will be able to labor and deliver in a pleasant environment with their families around them, when the unit is opened in several weeks.

The renovation and furnishings are gifts of Saudi Arabian Prince Alwaleed Alsaoud, 21, of Atherton, a student at Menlo College.

They are dedicated to his wife, Princess Dalal Saoud Alsaoud, who is expecting their first child, who will be born at Stanford. The rooms are not now ready to be used as an alternative birth center, and will be used initially by the donor family for a traditional birth.

"The hospital's administration is receptive to the idea of an alternate birth center because of the need for one expressed by the community," according to Duane Walker, R.N., associate administrator of the hospital and director of nursing service.

The rooms feature carpeting, oil paintings, and easy chairs that rock. One room has a standard hospital bed, with blue linens and comforter, a home-like chest of drawers and lighting fixtures, decorative ceramic figures, and window blinds that match the decor.

The other room includes a sofabed and refrigerator.

According to Karen Richards, R.N. who coordinated the redecorating project, the Prince wished to renovate the rooms for the use of all patients desiring alternative birthing, and to redecorate them as an appropriate and tasteful environment for other patients.

His offer, according to Ms. Richards, coincided with the hospital's plans already underway for an alternate birth area.

Added equipment and cabinetry will be necessary to enable the rooms to be used for that purpose. All materials, says Ms. Richards, will comply with hospital quality and standards.

She noted that donations toward equipment, research, or renovation of physical space in the hospital have always been welcome. She cited similar donations by former patients and their families of waiting rooms for intensive care and cardiac care areas.

Stanford already offers several alternative birth procedures, including rooming in and visits by children. Some of the procedures were implemented last year on the recommendations of the Hospital's Perinatal Care Committee, and the Birth Action Council, a group of parents in the community who have given birth at Stanford.

Dr. Elizabeth D. Hay, professor of anatomy at Harvard Medical School, will present the fifth annual Katharine D. McCormick Distinguished Lecture on Thursday, April 20 at 4:15 p.m. in the Fairchild Auditorium of Stanford University School of Medicine.

She will discuss "Tissue Interaction in the Developing Cornea." Members of the medical community and the public are invited to attend.

Hay has pioneered in the use of the electron microscope to investigate the biochemical processes of differentiation. Among her important studies is the synthesis of collagen in embryonip tissues, such as the cornea.

A graduate of The Johns Hopkins University School of Medicine, Hay held positions at Hopkins and Cornell Medical College before coming to Harvard in 1960. She has been chairman of the Department of Anatomy at Harvard since 1975.

Hay is a member of the American Academy of Arts and Sciences, and president of the Society for Developmental Biology. She has served as editor-in-chief of *Developmental Biology* and is a former president of the American Society for Cell Biology.

The McCormick Lectureship was established in 1974 for the purpose of bringing outstanding women physicians and scientists to Stanford.

The lectureship honors the late Katharine Dexter McCormick, who left a large bequest to the Medical School, particularly "for the encouragement and assistance of women in pursuing the study of medicine, in teaching medicine, and in engaging in medical research."

STANFORD—

A $1.2 million damage suit has been filed against Stanford University Hospital by a current employee who claims he was demoted and another who claims he was forced to resign.

The suit, which was filed in Santa Clara County Superior Court by employee Conroe C. McGee and ex-exmployee Frank P. Petta, seeks $100,000 in general damages and $500,000 in punitive damages for each of the men, as well as any special damages decided upon by the court.

In addition to the hospital and 20 John Does, three men named as defendants in the case are facilities director James P. McNally, chief engineer William G. Ferguson, and general foreman David M. Dominguez.

Stanford Hospital officials denied that the Hospital has acted improperly in dealing with the personnel actions taken concerning Petta and McGee.

McGee, who has been a hospital employee since 1968, alleges in the suit that he was asked to accept a demotion by McNally on Jan. 24 so that Dominguez could be named general foreman. McGee refused, although Dominguez was later named to the post.

In the suit Petta alleges he was forced by McNally to resign as chief engineer on January 13. Petta had joined the hospital staff in August 1976.

Because of an alleged poor job performance rating given by McNally, Petta claims he has been unable to find work.

The suit also alleges that the defendants McNally, Ferguson, and Dominguez "agreed among themselves to engage in a systematic process of diverting materials and labor from Stanford University Hospital construction projects for their individual and mutual use and benefit and to assist one another in obtaining positions of higher authority within Stanford University Hospital."

McNally, Ferguson, and Dominguez also have denied charges of any wrongdoing.

STANFORD—

A court ruling which declares state capitation grants to private medical schools unconstitutional will be appealed, according to a Stanford University official.

"I expect that the University will request the State Supreme Court to review the matter," said John J. Schwartz, University counsel.

The unanimous ruling Monday, (April 10), came in a suit filed by Stanford against the state treasurer and controller to collect $448,800 in capitation support owed to the University for increasing its medical school enrollment.

The ruling by the Third District Court of Appeal struck down the program run by the State Scholarship and Loan Commission which pays up to $12,000 for each student enrolled above a number fixed by the school's 1970-71 enrollment. The program was set up by the California Legislature for the purpose of increasing the number of physicians in the state.

Stanford did increase its enrollment by 35 students in 1973 and 26 students in 1974 and was paid. But when a similar application was submitted for 44 students enrolled in 1975, the state controller cut off the funds.

The controller claimed the payments may violate the state constitution which prohibits state support to schools with church ties or to any school not under the exclusive control of the state.

Stanford, which expanded its medical school enrollment beyond the levels called for in its contract, argued that bona fide contracts serving important public purposes were not "support" under the terms of the California constitution.

The state program was established when the Legislature found it would be cheaper to train physicians in existing medical schools than to build new ones.

Stanford has received $600,000 in state funds so far.

STANFORD--Two surgeons at Stanford University School of Medicine have been appointed to endowed professorships.

Dr. John A. Collins is the holder of the Walter Clifford Chidester and Elsa Rooney Chidester Professorship in Surgery, and Dr. James B. D. Mark has been named to the Johnson & Johnson Chair in Surgery.

Collins headed the U. S. Army surgical research team in Vietnam which studied shock and derangements of blood clotting mechanisms in wounded personnel. His research helped define basic mechanisms of the body's response to severe injury.

Collins, who is chairman of the Department of Surgery, received his medical degree from Columbia University, College of Physicians and Surgeons in 1959. He completed his residency training in surgery at Columbia-Presbyterian Hospital, New York in 1965.

Before joining the Stanford faculty in 1977, Collins held appointments at Washington University, St. Louis, Mo., Columbia University and the Walter Reed Army Institute of Research.

He presently serves on the editorial boards of three prestigious journals in the field of surgery as well as major committees including the expert panel on review of blood and blood products of the U. S. Food and Drug Administration, and as chairman of the Pre- and Postoperative Care Committee of the American College of Surgeons.

Mark, who heads the Division of Thoracic Surgery, has a special interest in pulmonary and esophageal surgery.

A 1953 graduate of Vanderbilt University School of Medicine, Mark completed his residency training in thoracic, cardiovascular, and general surgery at Yale-New Haven Hospital, Connecticut in 1960.

Prior to coming to Stanford in 1965, Mark held appointments at Yale University School of Medicine and in the U. S. Public Health Service. Awarded a Fulbright-Hays fellowship, Mark spent the 1972 academic year as visiting professor of surgery at the University of Dar es Salaam in Tanzania.

Mark is president of the executive committee of the California Academy of Medicine and a member of the governing body of the Health Systems Agency of Santa Clara County. He is past president of the Santa Clara County Medical Society, a former chairman of the department of surgery at Santa Clara Valley Medical Center, and was acting chairman of the department of surgery at Stanford from 1974-77.

Funds for the Chidester professorship were donated by the late John Hartman Chidester in memory of his parents, Dr. Walter Clifford Chidester and Elsa Rooney Chidester.

Dr. Chidester supervised the construction and activation of Mills Memorial Hospital in San Mateo and was chief of staff until the time of his death in 1936. Mrs. Chidester graduated in 1906 from the Lane Hospital Training School for Nurses conducted by Cooper Medical College--later to become the Stanford University School of Medicine. She died in 1972.

The Chidester chair was previously held by Dr. Roy B. Cohn, emeritus professor of surgery.

The Johnson & Johnson professorship was established in 1975 by the health care firm in order to help improve the quality of patient care, reduce hospital costs and develop a high level of medical proficiency and skill.

STANFORD—

Sleep research scientists honored science fiction writer Ursula K. Le Guin during the annual meeting of the Association for the Psychophysiological Study of Sleep on April 7.

Le Guin was recognized for the "best portrayal of sleep research in a work of fiction."

This was the first time the 200-member group of sleep researchers from throughout the world chose to honor a novelist, rather than one of their own members.

Le Guin was cited for two novels: *The Lathe of Heaven* (1971) an adventure story describing sleep laboratories and the life of the sleep researcher, and *The Word for World is Forest,* (1976), about the function and potential of dreaming.

Daughter of the Alfred Kroebers, Le Guin is a native of Berkeley, and has published nine science fiction novels since 1966, including *The Left Hand of Darkness* 1969, and *The Dispossessed,* 1974. Both received a Hugo Award for best novel.

Of some 14 volumes of fiction, her most recent is a short story collection, *Orsinian Tales.*

According to Dr. Rosalind Cartwright, leading dream researcher, "after 20 years of work we have found the answers to the big questions about dreams hard to come by. We are still asking, do dreams have any function?

"Ursula Le Guin has taken these questions and written 'what if' answers: what if people could use their dreams to regulate their feelings; what if dreams did change the world, and could occur on demand, preprogrammed?"

Cartwright suggested the researchers take up the challenge of Le Guin, to "recognize we have an inner world of emotional responses to explore, and the tools to do it."

FOR IMMEDIATE RELEASE

STANFORD—

Two new behavioral studies to help people stop smoking and lose weight at home are being conducted by the Stanford Heart Disease Prevention Program.

If they are successful, the studies could provide a more cost-effective way to reduce risk factors in the development of heart disease among the general population.

"Traditionally, self-help strategies were used in clinics," says Dr. Brian Danaher, director of the studies. "But it's too expensive to have professional consultants always seeing people.

"In addition, surveys have shown that a significant group of people would rather cut their smoking and weight at home. They're more likely to participate when they don't have to make a weekly trip to the clinic."

The studies begin April, 1978, and will run for eight weeks. Participants will come into the clinic for an initial evaluation and receive materials in self-help which they can follow at home.

Smoking cessation consists of three phases. In the first phase, participants prepare to stop smoking by learning relaxation techniques and monitoring the number of cigarettes smoked and the number of urges to smoke.

Next, they learn to stop smoking by focusing on the unpleasant aspects of normal smoking.

After they have stopped, they learn to deal with and eliminate lingering smoking urges. This is the maintenance phase.

Weight reduction emphasizes learning new skills to balance the energy in food which enters the body with that which is used up through exercise.

"We recommend that participants cut down caloric intake at the same time they increase their physical activity," sas Danaher. "But this balance depends on the particular needs of the individual."

Participants will be evaluated three and six months after the end of the studies. The results of the studies will be compared with those usually obtained in clinics, says Danaher.

Danaher says 60 volunteers are needed for each self-help program. Persons interested in participating should call the Stanford Heart Disease Prevention Program, 324-8147 or 324-8018.

STANFORD—

Hypnotic, or sedative, drugs are overprescribed for the treatment of sleep problems, according to Dr. William C. Dement, director of the Stanford Sleep Research Center.

"Treatment with any hypnotic drug is often inappropriate and sometimes harmful," says Dement. Recent studies indicate that the use of hypnotics might be associated with 0.6 percent or more of total population mortality.

More than 40 million Americans suffer from, or at least complain of, insomnia, Dement reported at the opening session of the annual meeting of the Association for the Psychophysiological Study of Sleep on April 5.

Sedatives may be appropriate treatments for only the minority of persons who complain of insomnia, says Dement.

Commonly, he says, insomnia is associated with depression, and antidepressant treatments or psychotherapy may be more effective than sleeping pills.

"Current data suggest that some popular hypnotic drugs are sufficiently dangerous that they should not usually be chosen to treat insomnia. These include pentobarbital, amobarbital, secobarbital, phenobarbital, glutethimide, ethchlorvynol, methyprylon and methaqualone.

Dement called for a "clear consistent rationale for treatment of insomnia," and said more research is needed into the longterm safety and efficacy of sleep-inducing drugs.

Dement was recently named to serve on the Institute of Medicine's Committee on Appropriate Use of Barbiturates: Options for Medical Practice. The study will deal with the overuse of drugs in general, and recommendations will be made to the Office of Drug Administration Policy of the National Institute of Drug Abuse.

Clinical longterm assessments of hypnotic drugs should be given immediate research priority, says Dement. He called for both studies using all-night sleep recording equipment, and larger-scale studies of morbidity and mortality.

FOR IMMEDIATE RELEASE
STANFORD—

Sleeping and dreams are an "emotional thermostat" which contributes to feelings and performance during the waking hours, according to two noted American sleep researchers.

This thermostat may get "stuck" during traumatic events, and can result in prolonged periods of depression, said Drs. Rosalind Cartwright, professor of psychology at Rush Presbyterian-St. Luke's Hospital and Medical Center in Chicago, and Milton Kramer, director of the sleep laboratory at the Veteran's Administration Hospital in Cincinnati.

The researchers reported their findings at the 18th annual meeting of the Association for the Psychophysiological Study of Sleep April 5 at Stanford.

One common example of emotional trauma which can linger for a long time is the death of a woman's husband. In addition to depression, the woman's dreams may be very disrupted, said Cartwright.

She may have a series of repeating dreams which relive her husband's death. These may be followed by dreams in which she denies the death, and by masochistic dreams in which she blames herself. This "mourning period" can last for months, and even years.

"If dreams function to work through emotional material," said Cartwright, "they are not working very well in these depressed women. If we could get at the unconscious material while it is in action, during the dream, and change the program, we may be able to shorten the mourning period."

Cartwright calls the reprogramming "dream shaping." It's a way of helping these women leave the past behind and orient to the future.

Cartwright first asks a woman who has been having a disturbing repetitive dream to choose a "happy ending." If her husband has died recently, she may choose an ending in which she finds a new husband, or work which will keep her busy.

The woman then sleeps in Cartwright's laboratory. A microswitch is taped to her palm. When she begins the repeating dream, she signals the researchers by pressing on the switch.

The researchers respond with an audible tone. This signals the woman to change the ending of her dream.

This technique has been tested in both normal and depressed subjects. Cartwright said the sleeping subjects were able to signal when they were dreaming twice as accurately as the researchers who were measuring rapid-eye-movement (REM) sleep with a polygraph. REM sleep is associated with dreams.

Using this technique, "we've been tailor-making happy endings for post-divorce women who are depressed and who are having disturbing dreams," said Cartwright.

Cartwright cautioned that the study was preliminary. "We're still trying to develop methods of dream shaping," she said.

It has been know for many years that persons can reshape their own dreams, said Kramer. But this knowledge is largely anecdotal. Cartwright's work is important because "it will help us know if we're dealing with a general process of one so highly variable that it could happen by chance."

Repetitious dreams resulting from trauma are like a needle stuck in a single groove in a record, said Kramer. Dream shaping "is a way of lifting up the needle and letting the record play itself out more effectively," he said.

FOR IMMEDIATE RELEASE

STANFORD—

When children lose a full night's sleep, their performance the next day is significantly impaired, Stanford sleep researchers say.

Another finding from the Stanford Summer Sleep Camp is that teenagers seem to need more sleep than younger children.

The findings were reported at the 18th annual meeting of the Association for the Psychophysiological Study of Sleep, being held April 4-9 in Palo Alto.

During the past two summers, groups of children ages 10 to 14 volunteered to spend several days living on the Stanford campus while sleep researchers monitored their naps and night time sleep patterns with polygraph machines.

The project is one of the first investigations of children's sleeping behavior. Funded by the Spencer Foundation of Chicago and the William and Flora Hewlett Foundation the study was sponsored by Drs. William C. Dement, professor of psychiatry and behavioral sciences, and Thomas Anders, head of child psychiatry in the medical school.

The children, according to Mary Carskadon, research assistant for the project, were healthy and had no sleep problems. By studying them, she said, researchers hope to be able to define normal sleeping behavior.

Each group of children spent six days at the "camp." Three times a day they took performance tests involving addition, word-memory, and listening skills. When not being tested, they were kept entertained with a variety of games and activities.

Researchers found that one night of total sleep loss in children significantly impaired their performance and resulted in an increased sleep tendency.

According to Carskadon, sleep tendency was measured at two-hour intervals during the day, with subjects at those times instructed to "close your eyes, lie quietly, and try to fall asleep."

Although several performance measures showed complete recovery after one full night of sleep (10 hours), sleep tendency and performance on an addition test did not return to previous levels until after two full nights of recovery sleep.

In another study, the sleep of 19 children ages 10 to 14 was compared to that of college students aged 18 to 21. Preliminary results suggest that an increased sleep tendency accompanies the physical maturation of adolescence.

"This really just affirms an old wives' tale," says Carsdakon, "that teenagers seem to need more sleep than younger children."

FOR IMMEDIATE RELEASE

STANFORD—

Persons with hypersomnia sleep apnea one day may be identified by the way they snore.

Dr. Elliot D. Weitzman and his colleagues at the Sleep-Wake Disorders Unit of New York's Montefiore Hospital have found that time-related patterns of snoring differ between normal persons and those with sleep apnea.

This study was reported at the 18th annual meeting of the Association for the Psychophysiological Study of Sleep April 4-9 at Stanford.

Sleep apnea, or frequent cessation of breathing during sleep, afflicts an estimated 100,000 people in the U.S., according to Dr. William Dement, director of Stanford's Sleep Research Clinic.

The condition is characterized by excessive day-time sleepiness, loud snoring and often by high blood pressure and an abnormal heart beat during sleep. In adults it typically occurs in middle-aged, overweight males.

In extreme cases, breathing may stop during sleep for two minutes or more, but most patients stop breathing for 30 to 50 seconds. The condition may result in heart attacks or sudden death during sleep.

"It is important to evaluate snoring patterns in order to diagnose what might be termed 'malignant' from more benign forms of snoring," said Weitzman.

Weitzman and his colleagues indicate that snoring patterns in patients with sleep apnea were serious because the illness is associated with high blood pressure, a risk factor in the development of heart disease, as well as cardiac rhythm abnormalities.

Hypertension may be caused by sleep apnea, he said, since reversal of the condition in some patients results in a rapid lowering of blood pressure.

Sleep apnea is identified by measuring changes in physiological signals of various body functions during sleep with a technique called a polysomnograph.

The polygraph machine used to make these measurements simultaneously and continuously records changes in the electrical activity of the heart (EKG), brain waves (EEG), eye movements, muscle tone, respiratory pattern and oxygen blood levels as the patient sleeps.

Weitzman and his colleagues have studied more than 50 patients with polysomnographic recording. It was found that those with severe obstructive sleep apnea have a type of apnea in which the throat muscles repeatedly open and close during sleep and obstruct the flow of air in and out of the lungs.

Audio tape recordings were made of breathing and snoring patterns in seven individuals for three to three and a half hours during sleep.

Three of the seven patients with sleep apnea had snoring patterns which were clearly distinguishable from the normal subjects.

The abnormal patterns consisted of snoring followed by relatively silent periods during which the patients did not breathe but had brief gasping sounds produced by ineffective attempts to breathe.

In normal subjects who snored during sleep, a snoring sound was present with each breath. Their patterns did not exhibit the silent periods nor brief gasping sounds.

These preliminary results suggest that audio records of snoring may be a practical and easy method for the initial screening of patients who complain of sleep apnea symptons or individuals with severe night-after-night snoring, said Weitzman.

FOR IMMEDIATE RELEASE

STANFORD—

The cyclic recurrence of dreams during sleep may be due to the opposing actions of two groups of nerve cells located in the brain stem.

Studies by researchers in the neurophysiology laboratory at Harvard Medical School support this theory. Drs. Ennio Vivaldi, J. Allan Hobson and Robert L. McCarley have found that drugs which affect these cells can either extend or shorten the periods of dreaming, or rapid-eye-movement (REM) sleep.

The Harvard group reported their findings at the 18th annual meeting of the Association for the Psychophysiological Study of Sleep April 6, 1978 at Stanford.

The brain generator for dreaming is like an electric motor controlled by an "on" switch and an "off" switch. When the "on" switch or nerve cells are turned on, dreaming sleep begins. When the "off" switch or nerve cells are turned on, dreaming sleep stops.

Nerve signals are carried from the brain stem to the cerebral cortex, the conscious part of the brain, by electrical impulses and by chemical messengers, called neurotransmitters. Neurotransmitters bring the electrical signals across gaps between the nerve cells.

"If this model of REM sleep is accurate, we ought to be able to increase the REM periods by turning on the 'on' cells," said Hobson. The researchers did this in cats by injecting a drug which mimics the chemical messenger of the "on" cells. The drug, carbachol, "produces a very dramatic enhancement of REM sleep," he said.

The researchers also enhanced REM sleep by giving a drug which prevented the natural breakdown of the "on" chemical messenger.

With another drug which blocks the actions of the "off" cell chemical messenger, "we see a three to four fold enhancement of REM sleep," said Hobson. The drug effectively disconnects the "off" switch of the dream motor.

- more -

The researchers are developing a new technique which will improve the study of drugs and dreaming sleep. They use an ionophoretic pump to propel very small and measureable quantities of drug into the brain. The pump is actually a micropipette charged by an electric current.

According to Hobson, the technique will enable them to determine exactly how much drug can stimulate a change in REM sleep, and whether injection of drug in a single cell can stimulate the whole group of cells to switch on. "We can bring pharmacology to the cellular level," he said.

These findings will have practical applications in understanding and treating narcolepsy, said Hobson. Narcolepsy is characterized by excessive daytime sleepiness. Persons afflicted with the disorder can suddenly collapse into REM sleep, especially when they are excited.

The present treatment of narcolepsy is based on increasing the activity of the "off" cells by giving amphetamines which mimic the "off" cell chemical messenger. The on-off switch model of dreaming sleep may provide further insights to understanding the disorder, said Hobson.

But the significance of the model goes "far beyond the realm of sleep," he said. "This is the first explicit model of a neural clock in mammals. It may indicate the way a number of other neural rhythms work, such as respiration and circadian rhythms.

"By providing a physical basis for dreaming, the model may also help us understand and treat psychoses."

The next fascinating question is why the recurrence of dreams occurs only during sleep. "It may be that the oscillators are damped during the waking hours," said Hobson. "But the mechanisms by which the dreaming sleep deactivator is deactivated remain to be investigated."

FOR IMMEDIATE RELEASE

STANFORD—

It's common to have repetitive dreams, says a leading sleep researcher, and the unpleasant ones seem to outweigh the pleasant two to one.

Dr. Rosalind D. Cartwright of the University of Illinois, Chicago reported these findings during the 18th annual meeting of the Association for the Psychophysiological Study of Sleep underway in Palo Alto. The meeting is sponsored by the Stanford Sleep Disorders Clinic.

In examining dreams described by 167 normal women, aged 18 to 55, the psychologist found that 65% reported having repetitive dreams—a same dream experienced three or more times.

Of the 220 dreams the subjects described, 61 were classified by Dr. Cartwright as pleasant and 159 as unpleasant.

Researchers also found a predominance of unpleasant dreams in an earlier study of 87 normal students, mean age 20.

In that study (coauthored with Dr. Irwin Romanek), 64% of the women and 54.5% of the men reported having repetitive dreams and could describe them. Bad or unpleasant dreams predominated, 63%, according to Cartwright.

In that smaller study, 77% of the women's repetitive dreams were unpleasant, but only 48% of the male's dreams.

The themes of the bad dreams included being attacked or threatened with injury or death—40%— and in 9% the subject was a helpless onlooker.

In 25% there was a "personal failure in some social role," and in another 25% there was some supernatural or other unpleasant experience.

- more -

Cartwright describes a "rough developmental or age sequence" of dreams. They are identified according to whether the cause or "agency" is inside or outside the dreamer, and whether the effect is good or bad.

"Bad-outside" dreams, she says, begin earliest, ages 5 to 12. Then "good due to own efforts" predominate at ages 9 to 12. "Bad due to personal inadequacy" dreams come later, ages 15 to 25.

Cartwright further classifies dreams into four categories: those concerning physical sensations, those with psychological components, social interactions, and others such as strange or supernatural dreams.

The commonest, or most frequent, of all dreams seems to be of the unpleasant social interaction type, she says.

These, she says, seem to begin early, ages 4 to 9, as aggression type dreams, such as being threatened by a tornado or a monster.

Psychological unpleasant dreams which begin in childhood rise to a peak at ages 16 to 21. In these the dreamer is frequently in competition, such as taking an exam, or in stress, such as having a school locker that won't open.

In older people, Cartwright has found "restitution" dreams, concerning visits with family or others who have died.

Cartwright believes that "dreams are not accidental—the interactions between dreams and the waking world are there."

Repetitive dreams, particularly, she says, are "indicators of areas of emotional importance, such as difficulties not being coped with adequately during waking.

"Dreams may be important in establishing the stable memory concepts to which new experiences are referred, and which help shape responses," she says.

She calls this processing of information "our regular night-shift work."

The psychologist plans future studies to examine the function of repetitive dreams of those who are under particular stress.

A future study will involve depressed, recently divorced women who have repetitive dreams.

FOR IMMEDIATE RELEASE

STANFORD—

An aspirin or two may help you sleep if taken occasionally, says a sleep researcher. But aspirin won't help sleep if it's taken habitually for more than three nights.

Drs. Peter J. Hauri and Peter M. Silberfarb of Dartmouth Medical School, Hanover, N.H., reported these findings at the 18th annual meeting of the Association for the Psychophysiological Study of Sleep underway April 4-9 in Palo Alto. The meeting is sponsored by the Stanford Sleep Disorders Clinic.

The researchers measured how fast study subjects fell asleep and how often they awoke during sleep after taking two aspirins nightly for up to two weeks.

Subjects were all serious insomniacs, says Hauri, who were without pain. Because the study was "double blind," subjects were not aware when they were receiving aspirin or a placebo, a similar-looking but inert substance.

According to Hauri, the sleep-inducing effects of the aspirin gradually lessened after three nights and finally disappeared.

"We conclude that two tablets of aspirin were an effective hypnotic medication during the first few nights of administration. However, aspirin lost much of its sleep inducing potency when used chronically for two weeks," they reported.

"This is exactly what happens with many other sleeping pills," says the researcher, though he indicates that the sleep inducing effect may last up to a month or two with some other drugs.

What Hauri called "rebound insomnia" seemed to be as pronounced with aspirin as with some other hypnotic drugs. "Rebound insomnia" is associated with withdrawal of the patient from the drug.

EDITORS—Cancer grabs the headlines as persistently as any movie star or politician. The word carries enormous emotional weight. It has been called the scourge of the Twentieth Century, killing more than 350,000 people in the United States each year.

Cancer is not one disease, but a collection of 100 to 200 of them. In the U.S., the afflictions range from lung cancer, which kills more men than any other cancer, to breast cancer, the top cancer killer among women, and leukemia, a cancer of the blood which strikes about 1,500 children annually.

This series of four articles deals with cancer care in the Stanford University Medical Center. Its purpose is to give an impression of the complexity of cancer and the whole array of medical forces lined up against it. The articles are: Hodgkin's disease— revolution in treatment, breast cancer—treatment for mind and body, research in immunology—seeking to resist cancer, and the Northern California Cancer Program—organizing the fight against cancer.

STANFORD—For the past four years, Jeanne McLane has been in and out of Stanford University Hospital frequently. She had lost an eye because of iritis, and then in June, a routine chest X-ray picked up a lump in the lymph glands in her chest. A biopsy was taken from the lump. The pathologist discovered Reed-Sternberg cells in the tissue sample. These peculiarly enlarged cells identified her lump as Hodgkin's disease.

Hodgkin's disease is a cancer of the lymphoid system which usually strikes between the ages of 20 and 40. About 8,000 new cases are expected in the United States this year. It frequently appears as a lymph node enlargement in the neck, chest, or abdomen, but it can involve many other tissues and organs.

"With my vision problem, I felt I had been dealt a rotten hand," says McLane. "But I said to myself, I can either turn to the wall and die or I can fight it. I've always been a headstrong person. I just decided it wasn't going to beat me."

Luckily, McLane has access at Stanford to the most up-to-date treatment for Hodgkin's disease presently available. As soon as the malignancy was confirmed by the pathologists, a team of specialists began to help her fight it.

First McLane went to diagnostic radiology for a lymphangiogram. This test uses an opaque dye, injected into the small lymph channels of the feet, to highlight the lymph nodes in the abdomen in X-rays. The test was negative.

- more -

Then she had a laparotomy and a splenectomy. These techniques involve surgical incision in the abdominal region to remove tissue samples from the liver and lymph nodes near the spine, and to remove the spleen for biopsy. They were all normal. The disease was limited to her chest.

These tests are called staging the disease. "In almost every cancer it is important to precisely stage the disease," says Dr. Ronald Castellino, chief of diagnostic, oncologic radiology. "A reasonable decision about treatment can be made only when the extent of the tumor is known.

"Under-treatment may result in the death of the patient. Over-treatment means overexposure to X-rays or drugs, or needless surgery, and may in itself affect the health of the patient."

Laparotomies were introduced as a diagnostic procedure for Hodgkin's disease at Stanford in 1961. Later, Dr. Henry Kaplan, D'Ambrogio professor of radiology, found that the spleen was a "silent seat of disease" that was being missed in treatments. Removal of the spleen does not affect the body functions and now is done routinely in the treatment of this disease. Surgical staging also is improving the treatment of other cancers, such as prostate cancer.

Because her cancer was caught early, McLane could receive treatments as a outpatient, commuting back and forth from her home. Her first treatment consisted of high-voltage radiation. She received 23 treatments from her head to her waist during a four-week period.

Three weeks later, she began taking four drugs used in the MOPP therapy for Hodgkin's disease. MOPP stands for the first letter of each drug; mustard, Oncovin (vincristine), procarbazine and prednisone.

This treatment program is the result of 15 years of work by Drs. Kaplan and Saul A. Rosenberg. It combines two major forms of cancer therapy—radiation and chemotherapy.

Dr. Kaplan helped design the first linear accelerator used in the treatment of cancer in patients in the Western Hemisphere in the late 1950s. "Radiotherapy now stands right along-side surgery as a major method for the permanent cure of many kinds of cancer," he says.

Dr. Rosenberg who directs the division of medical oncology helped establish the value and role of the MOPP treatment program. The division of oncology is now one of the largest in internal medicine.

Radiation and drug treatments have had a major impact on Hodgkin's disease. In the 1940s, only 25 percent of Hodgkin's victims survived five years. Today almost 90 percent of patients, including those with advanced cancer, are alive, without disease, five years after treatment.

"These results reflect the proper use of both chemotherapy and radiation therapy," says Rosenberg, "and even more than that, the teamwork of many disciplines working together."

Jeanne McLane probably will continue chemotherapy until June or July 1978. Then she will be able to take up a normal life again, but she will be watched by her physicians to make sure the cancer has been arrested.

Northern CA Cancer Prog

STANFORD UNIVERSITY MEDICAL CENTER
News Bureau Stanford, California 94305

FOR FURTHER INFORMATION CONTACT Bill Synder 415-497-6911

EDITORS: This is part four of a four part series on cancer care at Stanford University Medical Center. This article deals with the Northern California Cancer Program, organizing the fight against cancer.

STANFORD— "We have the ability and scientific knowledge to cure half the people with cancer today. We don't get every bit of knowledge to every patient, and, so we only cure about one-third.

"But even if we did that, we'd still lose half the patients with cancer. So, it is the role of research to try to close the gap from 50 to 100 percent," says Dr. Stephen Carter, director of the Northern California Cancer Program (NCCP).

Carter's goal is to close that gap and achieve 100 percent cure. His tool is the NCCP, a consolidation of 17 medical institutions which serve communities in Northern California and Northwestern Nevada.

"The NCCP, established in 1974, was a way of bringing together all cancer-related programs into a common family," says Dr. Saul A. Rosenberg, chairperson of NCCP's board of trustees.

"Many of the institutions dedicated to cancer research, care, teaching and training had never worked together before. They often duplicated each other's efforts. They were competitive, and often ignorant of each other," says Rosenberg.

Rosenberg, who also heads the division of medical oncology at Stanford University School of Medicine, directed the NCCP until Carter took over in 1976. Carter, 40, was former deputy director of the National Cancer Institute's cancer treatment division.

Carter calls the NCCP a center without walls. "We don't have beds or laboratories of our own," he says. "There is no need to build new resources if we can maximize the interaction of the resources we have in this region."

The NCCP is supported in part by grants from the National Cancer Institute. Some of the projects are still in the planning stage, but NCCP intends to launch a three-pronged attack on cancer through clinical research, basis science, and disease control.

Member institutions with clinical facilities including Stanford are initiating about 15 unified treatment programs for various cancers. If they are successful, says Carter, "these programs hopefully will bring forth newer and better treatment which ultimately can be applied to the general public."

Clinical research within the NCCP is done by the Northern California Oncology Group.

Stanford developed two treatment programs, those for head and neck cancer and oat cell cancer of the lung. A program for stomach cancer is being done jointly with the Japanese. It is the first example of a joint cancer study between U.S. and Japanese institutions.

The second NCCP front in the cancer battle is basic scientific research, specifically, the development of new anti-cancer drugs. Four member institutions, Stanford, University of California, San Francisco, University of Nevada, Reno, and SRI Internatinal in Menlo Park, are participating.

"Our aim is to develop resources through the interaction of NCCP members which none could develop on their own, a two-plus-two-equals-five arrangement," says Carter. Dr. Martin Apple of UCSF directs the drug studies program.

One of the first projects will be improving the effectiveness of the anthracycline drugs, such as adriamycin, and eliminating their side effects.

The third aim of the NCCP is cancer control. This is the field work, the application of research developments to reduce cancer deaths.

Cancer control will be mediated through six regional units (Sacramento, Reno, Santa Clara County, East Bay, Fresno, and North Counties), and by interaction programs. These include community outreach, education, rehabilitation, communications, epidemiology, and evaluation.

"We can't sit here in Palo Alto and know what is best for Reno which is different from Sacramento which is different from Fresno," says Carter. "They've got to do that themselves. We can hopefully offer them expertise and centralize resources."

Ideally, says Carter, "we will develop a new drug, do the clinical research to see that it's effective, and if so, see that it gets to every cancer patient in the state of California."

Some of the big cancers remain killers. There has been essentially no improvement in survival rates among patients with lung and pancreatic cancer for the last 30-40 years. Yet the lessons learned from other cancers such as Hodgkin's disease are being applied to other forms of the disease. "What has been accomplished in Hodgkin's disease could be called a revolution in the prognosis, or outcome, of that kind of lymph tumor," says Dr. Henry Kaplan, D'Ambrogio professor of radiology at Stanford. "We are continuing with out efforts to improve the outcome of other lymph tumors. We will not be finished until we are able to cure them all."

FOR FURTHER INFORMATION CONTACT: Bill Snyder 415 497-6941
EDITORS: This is part two of a four part series on cancer care at Stanford University Medical Center. This article concerns breast cancer—treatment for mind and body.

STANFORD—

When K.Kay Lewis found that she might have breast cancer, she was terrified. "I walked 50 blocks from the doctor's office to the hotel so I wouldn't start screaming in the taxi," she says. Lewis, 34, teaches high school English in San Jose. Last May a lump in her breast was discovered during a visit to New York. Her husband, Bill, was visibly shaken when she told him that her mammogram, or breast X-ray, looked suspicious. "He looked like an animal in a cage," she said.

Breast cancer strikes about 90,000 women in the U.S. each year. Only 62 percent of them will be alive for five years. Ten year survival drops to 49 percent.

The Lewises came to Stanford for further testing because both of them had lived in the area for 10 years and they felt she would get better care here. Extensive tests, including blood work, bone scans, and X-rays, showed that the tumor had not spread from her breast.

During the three days of testing, the Lewises sought the advice of physicians for the best treatment. They talked with radiotherapists about her pathology reports and X-rays, and discussed the possibility of radiation treatments, including a new treatment—the radiation implant.

The implant technique involves placing beads of radioactive iridium into parallel rows of nylon tubes which have been pulled through the breast. In this way, a high dose of radiation, which would damage adjacent tissue if given as an external beam, is presented to the localized area of the tumor.

Dr. Don Goffinet and Alvaro Martinez of the division of radiation therapy have implanted radiation beads around tumors of the breast, head and neck, lung, prostate gland and abdominal region for the past three and a half years. The success rate for control of localized tumors which have not been treated previously is close to 100 percent.

"Implants offer an alternative to very radical surgery which may alter function or produce a deformity," says Dr. Martinez. "Survival is important. But so is the quality of survival."

But Lewis chose to have the mastectomy (surgical removal of the affected breast tissue). "I was more afraid of the side effects of radiation than surgery," she said."I didn't fully understand the devastating psychological side-effects of mastectomy at that time."

The operation, performed by Dr. John L. Wilson, professor of surgery, and chief surgery resident, Dr. F. Anthony Marzoni, Jr., was a modified radical mastectomy. The diseased right breast and lymph nodes, but none of the chest muscle, were removed.

"I did beautifully," says Lewis. "I was the bravest patient Dr. Wilson had. The morning after surgery, I was up with my makeup on having tea before the doctors arrived on rounds."

Then the brave act began to fall apart. Bill left for an accounting job in Brazil. The household was spread between California and New York. And Lewis felt very alone.

"I would cry often," she says. "I stopped sleeping and eating. I'd tell myself I was all right, but I didn't feel all right. Everything became very vague. When people called my name, I felt like turning around and saying, 'she's not here.' "

Then she called Dr. Netta Grandstaff, a psychologist with the division of clinical social work. Dr. Grandstaff counseled her on a one-to-one basis, and brought her into a support group of women who had also had mastectomies.

"There is a large sisterhood among women who have had this surgery," says Lewis. "There is strength in realizing you are not alone."

Dr. Grandstaff's work began about four years ago and complements the reach to Recovery Program, in which breast cancer patients are visited in the hospital by women who have also had mastectomies.

In addition, social workers in medicine, oncology, surgery and radiology give support to patients with other forms of cancer. "The social worker is a valuable part of the health care team," says Dr. Frank Stockdale, professor of medicine, who treats many breast cancer patients.

The social worker helps the physicians plan a therapy which will treat the whole patient, not simply his or her disease.

"Dr. Wilson put my body back together," says Lewis, "but Dr. Grandstaff made me well."

Lewis is now living in New York with her husband. They will return to San Jose this year, and she plans to resume her teaching. She also will be actively involved in the support group at Stanford.

"It is unlikely that the disease will come back," she says. "But even if it does, I now have the emotional support to cope with it."

EDITORS: This is part three of a four part series on cancer care in the Stanford University Medical Center. This article concerns reearch in immunology—searching for ways to prevent cancer.

STANFORD—

One person out of four in this country will get cancer sometime in his of her lifetime. That person may smoke a lot, or work in a coal mine, or eat large quantities of fish. He or she may have been exposed to aniline dyes used in early color photography or to high levels of radiation. Or the person's genes may allow a cancer to gain a foothold in the body and grow.

It is becoming more apparent to scientists that genes and the immune responses they control to some extent determine the susceptibility and resistance to several diseases, including cancer.

Indirect evidence of this is found in the association between other diseases and antigens, markers which are found on cell surfaces in all tissues. The presence of antigens on red blood cells can be determined by blood cell typing.

The antigens are like badges which enable white blood cells to distinguish between body tissues and foreign materials such as bacteria, viruses and organ transplants. When a foreign agent is identified, an immune response is mounted against it.

But markers on the surfaces of white blood cells also are associated with 35-40 diseases, including ragweed hay fever, arthritis, juvenile onset diabetes, multiple sclerosis, psoriasis, and cancers such as acute lymphoblastic leukemia and Hodgkin's disease.

Perhaps the best example is ankylosing spondylitis, a rheumatic condition which can result in the fusion of the lower spine. Over ninety percent of the persons afflicted with this disease carry cell surface antigens called B27.

The B27 marker also is associated with Reiter's syndrome, a form of arthritis which can follow bacterial infections such as Shigella dysentary. "Eighty percent of persons with Reiter's syndrome which developed after Shigella dysentary carry the B27 type," says Dr. Hugh McDevitt, professor of medicine at Stanford

Carriers of the B27 markers are like pre-set fuses. A bacterial infection simply lights the fuse that explodes into disease.

Another example is juvenile onset diabetes, a form of the disease which occurs early in life. "There is suggestive evidence that this form of diabetes occurs in persons with a certain cell surface antigen marker (D3) after they have been exposed to a common virus infection," says McDevitt.

Eventually, says McDevitt, it may be possible to interfere with the pre-set program by immunizing against the viruses and bacteria associated with the diseases in susceptible persons, those with markers like B27 or D3.

- more -

"However, nobody knows the cause of diabetes or arthritis, or many of the disorders, called autoimmune diseases, which involve an attack by the body upon itself," says McDevitt.

"In addition, we haven't yet worked out methods of tissue typing as well as red blood cell typing techniques."

Red blood cell typing is a chemical test which can be performed in minutes to detect the presence of certain antigens on red blood cells. Complete tissue typing of white blood cell markers, on the other hand, requires the use of 100-150 typing sera, and culturing the patient's blood with that of 15 other patients of known type for five days. It is too expensive and time-consuming to perform on a mass scale.

"The real progress in preventing these diseases will be made when we can get to the root of the problem—the genetics," says McDevitt.

In the early 1960s, McDevitt discovered that immune responses in mice were controlled by genes which were closely correlated with genes responsible for the transplant rejection reaction. The transplantation genes also determine the structure of the white blood cell antigen markers.

These "immune response" genes discovered by McDevitt have also been identified in humans, and, as in the mouse, they are associated with the white blood cell antigen types.

In 1964, Dr. Frank Lilly, currently the head of the Department of Genetics at Albert Einstein School of Medicine in New York, discovered that susceptibility to a leukemia virus in mice was linked to these antigens.

Recently, Dr. Dan Meruelo, a postdoctoral fellow in McDevitt's lab, has found that two distinct forms of a single white blood cell antigen can connote either suscepibility or resistance to a leukemia virus expressed in mice after radiation exposure.

Other studies suggest that genes may actually suppress the immune response to some tumors. Meruelo has located an immune response gene in mice which actively suppresses resistance to a leukemia tumor through a cell it produces. "This is one of the first discoveries of dominant immune suppression by a gene," says McDevitt.

Dr. Baruj Benacerraf of the Harvard Medical School has developed an anti-serum against these immune response genes which prevent their suppressive action. After injecting the anti-serrum in mice with implanted tumors every day for several days, he found that the tumors had disappeared and were replaced by inflammatory cells.

"It is not known if the anti-serum will work against already existing tumors," says McDevitt. At least five more years of study in the mouse are needed to validate these findings before scientists can think about applying it to humans, he says.

"We cannot promise any panacea," he says. "We are studying the regulation of the immune response at a fundamental level. But if we could work out all of the different white blood cell types, it is theoretically possible to alter the regulation and turn the immune response up or down to help people resist tumors or fight disease."

EDITORS: This is part four of a four part series on cancer care at Stanford University Medical Center. This article deals with the Northern California Cancer Program, organizing the fight against cancer.

STANFORD— "We have the ability and scientific knowledge to cure half the people with cancer today. We don't get every bit of knowledge to every patient, and, so we only cure about one-third.

"But even if we did that, we'd still lose half the patients with cancer. So, it is the role of research to try to close the gap from 50 to 100 percent," says Dr. Stephen Carter, director of the Northern California Cancer Program (NCCP).

Carter's goal is to close that gap and achieve 100 percent cure. His tool is the NCCP, a consolidation of 17 medical institutions which serve communities in Northern California and Northwestern Nevada.

"The NCCP, established in 1974, was a way of bringing together all cancer-related programs into a common family," says Dr. Saul A. Rosenberg, chairperson of NCCP's board of trustees.

"Many of the institutions dedicated to cancer research, care, teaching and training had never worked together before. They often duplicated each other's efforts. They were competitive, and often ignorant of each other," says Rosenberg.

Rosenberg, who also heads the division of medical oncology at Stanford University School of Medicine, directed the NCCP until Carter took over in 1976. Carter, 40, was former deputy director of the National Cancer Institute's cancer treatment division.

Carter calls the NCCP a center without walls. "We don't have beds or laboratories of our own," he says. "There is no need to build new resources if we can maximize the interaction of the resources we have in this region."

The NCCP is supported in part by grants from the National Cancer Institute. Some of the projects are still in the planning stage, but NCCP intends to launch a three-pronged attack on cancer through clinical research, basis science, and disease control.

Member institutions with clinical facilities including Stanford are initiating about 15 unified treatment programs for various cancers. If they are successful, says Carter, "these programs hopefully will bring forth newer and better treatment which ultimately can be applied to the general public."

Clinical research within the NCCP is done by the Northern California Oncology Group.

Stanford developed two treatment programs, those for head and neck cancer and oat cell cancer of the lung. A program for stomach cancer is being done jointly with the Japanese. It is the first example of a joint cancer study between U.S. and Japanese institutions.

The second NCCP front in the cancer battle is basic scientific research, specifically, the development of new anti-cancer drugs. Four member institutions, Stanford, University of California, San Francisco, University of Nevada, Reno, and SRI Internatinal in Menlo Park, are participating.

"Our aim is to develop resources through the interaction of NCCP members which none could develop on their own, a two-plus-two-equals-five arrangement," says Carter. Dr. Martin Apple of UCSF directs the drug studies program.

One of the first projects will be improving the effectiveness of the anthracycline drugs, such as adriamycin, and eliminating their side effects.

The third aim of the NCCP is cancer control. This is the field work, the application of research developments to reduce cancer deaths.

Cancer control will be mediated through six regional units (Sacramento, Reno, Santa Clara County, East Bay, Fresno, and North Counties), and by interaction programs. These include community outreach, education, rehabilitation, communications, epidemiology, and evaluation.

"We can't sit here in Palo Alto and know what is best for Reno which is different from Sacramento which is different from Fresno," says Carter. "They've got to do that themselves. We can hopefully offer them expertise and centralize resources."

Ideally, says Carter, "we will develop a new drug, do the clinical research to see that it's effective, and if so, see that it gets to every cancer patient in the state of California."

Some of the big cancers remain killers. There has been essentially no improvement in survival rates among patients with lung and pancreatic cancer for the last 30-40 years. Yet the lessons learned from other cancers such as Hodgkin's disease are being applied to other forms of the disease. "What has been accomplished in Hodgkin's disease could be called a revolution in the prognosis, or outcome, of that kind of lymph tumor," says Dr. Henry Kaplan, D'Ambrogio professor of radiology at Stanford. "We are continuing with out efforts to improve the outcome of other lymph tumors. We will not be finished until we are able to cure them all."

STANFORD—

The Stanford Arthritis Center is launching a long-term survey of persons with rheumatoid arthritis.

The researchers hope that 1,000 patients from throughout the Santa Clara Valley will participate in the ten-year effort to obtain information about the course of this disease.

The survey will be conducted only by mail or telephone, and no physical examinations are involved. Patients will be asked a series of questions about how they are getting along with the arthritis, how much pain and stiffness they are having, and how well they can do their daily activities. They will be contacted at approximately six-month intervals throughout the study period.

The study does not provide treatment or advice. Survey assessors will not be able to answer questions about the disease, and will refer the patient to his own doctor for such information.

The Stanford Arthritis Center, operating under a grant from the National Institutes of Health, was established under the National Arthritis Act of 1975.

Dr. Halsted Holman, professor of medicine at Stanford, is director of the Center, and Dr. James Fries, associate professor of medicine, is associate director. Fries is director of the American Rheumatism Association Medical Information System, a nationwide data bank.

According to the investigators, they will examine both the medical costs of the disease, and the social costs, such as interference with work activities. The role of different treatments in changing long-term outcomes for patients will be evaluated.

Both patients and their physicians will receive reports of the survey at periodic intervals. No physician or patient names will be included in the reports of the study.

Persons with rheumatoid arthritis who wish to participate may call the Arthritis Center, (415) 497-5138. Local pharmacies also will be posting information about the study.

STANFORD—Two researchers in the clinical pharmacology division of the Stanford University School of Medicine have been awarded grants from the Pharmaceutical Manufacturers Association Foundation.

Dr. Robert L. Blum, a postdoctoral fellow, is the recipient of a two-year grant scheduled to begin in July.

The project funded by the grant involves the development of methods for using computers to help diagnose and treat patients.

The project will use knowledge from expert clinicians as well as information from computerized patient records. The techniques used will be from a new branch of computer science called artificial intelligence, which utilizes the capabilities of the computer to manipulate symbols in order to simulate human reasoning processes.

The program will make therapeutic decisions by weighing costs and benefits of therapy.

Blum also will be working towards a doctoral degree in computer science.

David M. Carlisle, a second-year medical student working with Dr. Terrence Blaschke, has been awarded a medical student research fellowship.

Carlisle plans to study the interaction between warfarin, an anticoagulant, and vitamin K, required for the synthesis of certain blood clotting factors. He hopes to discover the mechanism by which warfarin interacts with vitamin K and interferes with normal clotting.

Carlisle hopes to pursue a career in academic medicine after completing medical school.

According to the Pharmaceutical Manufacturers Association Foundation, grants have been awarded to 57 individuals this year, and the Foundation has aided over 470 individuals since 1965. This year, awards total almost $1.2 million, distributed to university research and training programs.

STANFORD—Dr. Boris Peterlin, a resident in the division of immunology at Stanford University School of Medicine, has been granted a two-year,$31,000 special fellowship by the Leukemia Society of America, Inc.

Dr. Peterlin was "one of ten highly skilled individuals chosen for the award this year," the Society said.

Peterlin will be woking in the field of genetics, focusing on the study of immune-response genes in rats as they relate to leukemia.

A native of Yugoslavia, Dr. Peterlin received a bachelor of science degree in chemistry and physics from Duke University, his M.D. from Harvard in 1973, and did his postdoctoral work here at Stanford. He was a research assistant at the National Institutes of Health until 1975 and returned to Stanford in 1977 as a resident in Medicine, his current position.

STANFORD—"Stanford's Contribution to Medical Science" is the theme of this year's Medical Alumni Reunion Day Program to be held Saturday, June 3. The all-day program begins at 8:15 a.m. with registration in Fairchild Auditorium.

"National Health Insurance and the Cost of Medical Care" will be discussed at 1:30 p.m. in a keynote address presented by Alain C. Enthoven, Eccles Professor of Public and Private Management at Stanford's Graduate School of Business.

Special feature for the program is "The Barefoot Doctors of Rural China," a film and discussion at 3 p.m. by Victor H. Li, Shelton Professor of International Legal Studies at Stanford School of Law.

Morning lectures include "Heart Transplantation Ten Years Later," by Dr. Norman E. Shumway, Frances and Charles Field Professor and Chairman of Cardiovascular Surgery, at 9 o'clock, and "Endorphins" by Dr. Avram Goldstein, professor of pharmacology, at 10:30. Endorphins are brain peptides that mimic the activity of opiates. These compounds are providing clues that may serve to increase the understanding of emotional behavior, the biochemistry of analgesia, and narcotic addiction.

Dr. Hugh McDevitt, professor of medicine, will discuss "H-LA and Disease" at 11:30. His report will describe immune-response genes in man. These may be important factors in an individual's resistance or susceptibility to neoplastic, auto-immune, and infectious diseases.

STANFORD— Innovations in surgical procedures should be more closely monitored in order to permit "prompt and reliable evaluation of their efficacy and safety," according to a group of researchers writing in *Science* magazine.

Controls and regulations such as those imposed on new drugs, are not presently required for new operations, and a long-term program of surveillance for both new and established operations is lacking, according to Dr. John P. Bunker of Stanford University Medical School, Dr. D.W. Hinkley of the University of Minnesota and Dr. W. V. McDermott of Harvard Medical School.

The authors recommend a four-phase program designed to facilitate early evaluation and subsequent monitoring of surgical procedures. The program would be supervised by a proposed "Institute of Health Care Assessment."

The first phase of the proposed program would involve "feasibility studies" for new surgical techniques. During this phase of evaluation, the operation would be restricted for use at only a few selected institutions, and would be closely supervised and perhaps refined.

Following this initial phase, a second phase of evaluation would continue at a larger number of institutions, providing information on the "outcome of surgery carried out by surgeons with varying degrees of training and experience and in a variety of clinical settings."

The operation would be available for general use during the third phase of evaluation. During this period, observations would continue and data would be stored, providing valuable information on factors such as "age, sex, operation and discharge status."

Although the procedure would be in general use at this stage, it would still be confined to "institutions demonstrating personnel and facilities appropriate to the complexity of the procedure."

The fourth phase would involve low-level, long-term surveillance. Not only new procedures would be monitored in this way, but also "old procedures where professional uncertainty persists."

The authors illustrate the need for such a program with several examples.

In the case of the coronary artery bypass operation introduced in 1969, systematic monitoring could provide "data on the basis of which the relative success of all institutions can be judged," resulting in less duplication of health care facilities.

- more -

The small intestinal bypass operation used for treatment of extreme obesity is an example of an operation with an associated high mortality rate and serious possible side effects, according to the article. It is a tricky procedure which shortens the intestine, with the result that less food is absorbed. It is performed only in extreme or life-threatening situations. There is uncertainty among doctors as to whether to perform this bypass or the newer gastric bypass.

If comprehensive data were available for such competitive procedures, more sound decisions could be made on which operation to use, the authors add.

A type of surgery called portacaval shunt, used in the treatment of hypertension, illustrates how an operation may be performed for many years before it is recognized to be relatively ineffective.

This operation, designed to control hemorrhage, involves the creation of a passage between the portal vein and the vena cava. Complications from the surgery may be as serious as the original condition, but the limited value of the operation is just now becoming clear after several decades of widespread use. Systematic monitoring should prevent such a delay in evaluation, the doctors said.

Under the proposed program, all evaluation phases would be monitored by the "Institute of Health Care Assessment," which might be under the purview of either a private agency such as the Institute of Medicine or the American College of Surgeons, or a government agency such as the National Center for Health Services Research.

Advancement through each phase would be recommended by the Institute, as would selection and funding of institutions during the initial phases of review. Funding would be awarded to institutions on a competitive basis.

However, one danger the authors point out is "overly rigid control which may lead to premature evaluation." New procedures which show initial problems may, upon modification, become effective and successful.

Although evaluation is needed, the authors warn, "We must not overlook the central role of innovation."

STANFORD—A new center designed to apply engineering technology towards solving the problems of the handicapped has been established at the Palo Alto Veteran's Administration Hospital.

Called the Rehabilitative Engineering Research and Development Center, it represents a joint effort between physicians at the VA Hospital and engineers at Stanford University. Specific projects are contracted to University engineers by the VA.

The association between physicians and engineers at Stanford in the past has produced inventions such as the Optacon reading aid for the blind, an ultrasonic imaging system, and computerized monitoring of heart functions.

"The new center is putting 'Star Wars' technology directly into helping the human being," says Dr. Franklin G. Ebaugh, chief of staff for professional services at the VA Hospital.

"The goal of the center is to help the amputee, the blind and deaf person, and the patient with major physical disabilities to function more normally and more competitively," says Ebaugh.

Ebaugh, who is also professor of clinical medicine at Stanford medical school, helped prepare the proposal for establishing the center, one of two in the U.S. The other is located at Heins VA Hospital outside Chicago.

The Palo Alto center is supported this year by a $183,000 grant from the Veteran's Administration. Dr. Larry Leifer, associate professor of mechanical engineering at Stanford, is coordinator. The staff includes an engineer, an orthopedic surgeon, a research physical therapist, and an administrative assistant. According to Leifer, the center's proposal calls for an enlarged staff of 30 and a budget of $1 million by 1981.

One of the current projects involves adapting a robotic arm to the needs of handicapped people. The arm was developed by Victor Scheinman, an engineer at Unimation, Inc., and has been used by Leifer as a teaching tool in his product design course at Stanford. Students have programmed it to bake a cake, flip pancakes, pour a glass of wine, type and use the telephone.

The computer programming of the arm is now done through a keyboard, but eventually it will be done by voice command, says Leifer. In coming months, the arm will be introduced to patients at the VA Hospital and "we will begin to explore its usefulness in providing for patient needs," he says.

A portable personal information system which will enable a visually impaired individual to process, store and retrieve information, as well as communicate more efficiently with others, is being developed by John G. Linvill, professor and chairman of electrical engineering at Stanford, and Gregory L. Goodrich, staff psychologist at the VA Blind Rehabilitation Center, in collaboration with Martin Morf and John T. Gill from the Stanford school of engineering.

The system will employ a micro-computer equipped with programs for editing and text processing. Input devices will include both a standard typing keyboard and a Braille keyboard. One method of output will allow the visually impaired individual to "read" printed material shown on a TV-type screen with the aid of an Optacon, a device which translates light images into tactile images. Another system presents the output, one line at a time, in braille.

- more -

A major participant in the project is Greg Fowler, a blind graduate student in electrical engineering, who will utilize the test system for his own educational professional needs.

Goodrich is also working with Drs. James D. Meindl and Dave Dameron of the Stanford Electronics Laboratory, in developing an ultrasonic mobility aid for the blind. Essentially a miniature sonar system, fitted in thin strips across the lens of glasses, the device will sweep a column of sound in front of the user, and provide information about the distance and shape of on-coming objects. Echoes returning from the sound column will be translated into audible or tactile signals. The device would be used to complement guide dogs or long canes.

Dr. Inder Perkash, chief of the VA Spinal Cord Injury Service, and Professor Robert Piziali of mechanical engineering are studying methods of spine stabilization which ensure that the disrupted spine remains stable and heals without deformity, while at the same time allowing the patient early mobilization. These methods include the use of braces, body casts, and implantable traction rods.

"The basic concept of rehabilitative engineering is to have engineers and physicians working side by side," says Perkash, also associate professor of surgery at Stanford. The center is unique in that it involves not only engineering faculty but their students as well, he says.

Graduate students have met with therapists and patients at the VA Hospital to determine ways of solving the problems of disability through engineering.

Several student-built rehabilitative aids have resulted from these meetings, and are currently being tested by patients at the VA Hospital. These include a two handled spoon which can be used by persons with cerebral palsy, and a kitchen designed for patients confined to a wheel chair.

"These are relatively simple ideas," says Leifer, "but they probably would not have been investigated without the support of a program such as this." Leifer says extensive testing (three to eight years) is required before these devices are ready for distribution to the public.

The center initially will be geared to research, says Ebaugh. As the technology is tested clinically, residents and medical students at Stanford Medical Center will have a greater opportunity to work in rehabilitative engineering programs.

"These programs will create new interest among physicians in what has been a seriously neglected field," says Ebaugh. "With the advances in technology, the care of handicapped patients has become as exciting and challenging as the care of more acute patients."

A problem yet to be solved is how to get the technology from the clinical lab to the market place. "It doesn't do one bit of good to develop these devices if we can't get them manufactured or marketed," says Ebaugh. "To interest manufacturing firms in our devices, we must have licensing and patent agreements to ensure them a profit."

According to Ebaugh, the Veteran's Administration presently has no such agreements with the developers of rehabilitative devices, but it could follow a model used by Stanford and the Department of Health, Education and Welfare (HEW).

Under institutional patent agreements, Stanford has first option to license or patent any invention which results from research supported by the HEW. Income from royalties is used to support further research and education.

Although the initial expense of developing and implementing these rehabilitative devices will be high, says Ebaugh, "I predict they will more than pay for themselves in the long run by helping handicapped people become more self-sufficient."

Editors: This news story is released in conjunction with the meeting of the American College of Sports Medicine in Washington, D.C. May 24-27. This story is based on a report to be presented on May 26.

STANFORD--Athletes should have the least exposure to smog as possible just before a competitive event, so their performance won't be impaired, says a Stanford researcher.

Long distance runners, for example, may not have decreased performance during smoggy conditions if they undergo normal training but limit their exposure on the day of the event.

William M. Savin, formerly of the Human Performance Laboratory, Department of Physical Education at UC-Davis, reported on the effects of air pollution on strenuous exercise at the May 26 meeting of the American College of Sports Medicine in Washington, D.C. Savin is now a research assistant in cardiology at Stanford University School of Medicine.

The study measured exercise performance in ozone levels which would be classified as "alert" or "warning" smog levels. Savin described these as realistic levels, which have been exceeded on some days in Los Angeles.

Ozone is the primary constituent of photochemical smog, produced by the interaction of sun on auto exhausts. The ozone occurring naturally in the upper atmosphere is of a different source.

The study involved nine healthy men who pedaled a stationery bicycle as long as they could while breathing ozone concentrations of zero, .15 or .30 ppm.

The volunteers' mean age was 26, all had extensive athletic backgrounds, and were running competitively or jogging regularly at the time of the study. None smoked.

The men were not aware of the ozone concentration, if any, being administered.

Results show that exposure to as much as .30 ppm ozone during graded exercise resulted in no significant change in performance, although subjects reported symptoms of discomfort more frequently with increased ozone levels.

According to Savin, "The effects of ozone depend upon both the duration and concentration of exposure.

"Well-trained, motivated individuals experience physiologically measurable changes and report symptoms before any change in their duration of performance becomes apparent." Mailed 5/25/68

CITY DESKS: Photos available upon request if not included with story.

STANFORD—One Sunday afternoon, a month before his 22nd birthday, Robert A. Johnson was riding a motorcycle in a cycle park when, as he recalled, "I lost control and was thrown off, hit a tree and broke my back."

The accident left him paralyzed from the chest down and confined to a wheel chair. More fortunate than other victims of spinal cord injuries, Johnson retained the use of his arms.

Now 29 and living in Santa Cruz, Johnson drives to Palo Alto in a car equipped with hand controls for a periodic checkup at the Spinal Cord Injury Center of the Veterans Administation Hospital. Affiliated with Stanford University School of Medicine, the center provides hospital, outpatient and home care for persons with spinal cord injuries.

Road accidents involving autos and motorcycles are the leading cause of spinal cord injury, according to Dr. Inder Perkash, chief of the VA Spinal Cord Injury Center and associate professor of surgery at Stanford medical school. Bicycle related injuries account for a growing proportion of road accidents.

Diving into shallow water, falling from heights, and sports such as football and skiing cause spinal cord injuries. Combat injuries account for a small percent of the total, but in Veterans hospitals they have been highly significant in inspiring improvements in patient care.

"Rehabilitation, both physical and psychological, and reintegration of the veteran into the community, with concern for the quality of life" are the primary aim of the center, according to Perkash.

Immediately after injury, a medical team composed of a neurosurgeon, orthopedist, physiatrist (rehabilitation physician), internist and urologist provides acute medical care.

Stanford faculty and residents see patients at the center under an agreement between the VA and the university.

The center serves veterans primarily from Northern California, Oregon and Washington, but patients are flown in from as far as Alaska.

After the patient's condition is stabilized, the services of a plastic surgeon, physical and occupational therapists, psychologist and social worker are mobilized.

Depending upon the severity and location of the injury, spinal cord damage may cause varying degrees of paralysis. Paraplegia is paralysis of the legs and lower part of the body; quadriplegia involves paralysis of both arms and legs.

"Most patients were extremely active people who were prone to injury," noted occupational therapist, Daryl Wright. Therefore, tremendous physical and psychological adjustments must be made by the patients and their families.

While physical therapists work with patients in repositioning, strengthening and reeducating muscles and joints, occupational therapists, with the aid of specially designed self-care devices, help them relearn such seemingly simple tasks as eating, dressing and bathing.

- more -

Johnson, now a student at the University of California, Santa Cruz, emphasized that rehabilitation teaches patients how to live with their disability. Normally, people take body functions for granted, he said. Disabled persons must constantly monitor themselves to prevent complications from developing.

Articulate and outspoken, Johnson is vice-president of the Santa Cruz County Chapter of the California Association of the Physically Handicapped. Through CAPH, Johnson works to build support in his community for legislation and programs that will help "bring the disabled into the mainstream of society."

"As a youth, I didn't see many disabled persons," he said. "They were hidden. I didn't see them at social functions, concerts or parties. After I was injured, I realized it wasn't that they did not want to be in the mainstream of society, but that society discriminates against the disabled. There are transportation, architectural and attitudinal barriers."

Always interested in competitive sports, Johnson has not let his disability prevent him from engaging in athletics.

Last year, he was the only wheel chair entry in the six mile Wharf-to-Wharf race from Santa Cruz to Capitola. This year he will take pledges from donors in support of CAPH for each mile that he travels, and is encouraging other members to participate.

A serious problem associated with spinal cord injury is bladder dysfunction which may cause serious urinary tract infection and death. Catheterization, in which tubing is passed through the urethra to drain the bladder, may result in additional complications.

Perkash is known for his work in bladder rehabilitation. About 95 percent of all patients seen at the center return home catheter free--either through a program of intermittent catheterization which results in bladder rehabilitation, or by the surgical procedure of a sphincterotomy.

Reuben Day was 21 years old and in the Navy when, diving into a reservoir in the San Joaquin Valley, he hit the bottom and broke his neck.

Paralyzed from the neck down, Day was hospitalized at a VA hospital in Southern California for 14 months. Chronic bladder dysfunction so weakened Day who is 6 feet 2 inches tall, that his weight dropped to 115 pounds. Discharged from the VA hospital but unable to return home because of his poor physical condition, he moved into an apartment with an attendant, then into a "para-vet" home, and finally into a convalescent home.

The turning point for Day was when he heard about the Spinal Cord unit at the Palo Alto VA Hospital. After Perkash performed a sphincterotomy "my health shot up. Since then, everything has been going up hill. I began to live," Day recalled. Regaining his strength, Day returned home.

To help veterans such as Day and Johnson function independently and at their full potential, the center does research in collaboration with Stanford's schools of medicine and engineering, as well as Children's Hospital at Stanford. By utilizing the latest advances in scientific technology and medicine, increasingly effective procedures and devices are developed. Graduate students in the school of engineering are working on rehabilitative devices as part of their doctoral research. A new rehabilitative engineering research and development center will be developed at the Palo Alto VA Hospital as a result of such collaborative efforts.

Orthotic devices to provide corrective support and brace weak muscles and joints are continually being improved. A specially contoured seat that provides optimal weight distribution and prevents the development of skin damage and infection in paralyzed patients, has been developed by Wallace Motloch of the Rehabilitation Engineering Center at Children's Hospital.

- more -

Biofeedback devices monitoring otherwise imperceptible changes in muscle tension are used experimentally to increase patient awareness and muscle control, according to psychologist Michael Dunn.

"Environmental systems," controlled by sucking or blowing into a tube, enable quadriplegic patients to call a nurse, raise or lower a bed, operate a TV, wheel chair, or dial a telephone number.

The 30-bed spinal cord center which opened in 1974, admits about 250 patients a year. It is one of two in the country that offer physicians postresidency training in spinal injuries. Average length of stay at the center for newly injured paraplegics is four months. Quadriplegics remain about 6-7 months.

Non-veterans may be admitted to the center on a space-available basis, under a shared service agreement between the VA and Stanford. In practice, however, the unit has difficulty accomodating private patients because the demand among veterans for its services is so great, Perkash noted.

In addition, 800-900 outpatients are seen at the center. "With spinal injury patients, one never terminates their care," Perkash commented. To prevent rehospitalization, former patients are seen in the outpatient clinic for periodic checkups. As a result, the center has the lowest readmission rate in the entire VA system, according to Perkash. In a recent nationwide survey of patient satisfaction in VA hospitals, the Palo Alto Spinal Cord Injury Center received the highest rating.

To ease the transition from hospital to home, the center operates a program of "hospital based home care." A physician, nurse, health technician and social worker visit patients and their families who live within 50 miles of the hospital.

Furniture arrangements, bathroom fixtures, kitchen appliances and utensils, telephones are evaluated for accessibility and ease of operation, and may be redesigned, if necessary.

Patient and family are given an opportunity to discuss any problems that may have arisen since discharge. "Anxiety levels are high. We try to provide emotional support," nurse Vicki Wolfe noted. "Often, letting them know you care means more than changing a dressing."

The social worker makes sure that available benefits are received by the family and that community resources are mobilized. Discharged patients often fear to go out and face the community, social worker Elise Richter acknowledged, but "once out, the majority don't want to come back."

Reuben Day now lives in Stockton in a home designed by himself that is especially adapted to meet his needs. Highly motivated and determined, Day is a science and math major at San Joaquin Delta College. After graduation he plans to pursue a career in business.

Day has limited use of his arms and hands. However, tendon transfers performed by a plastic surgeon have improved his hand function, and he hopes to drive a specially equipped van.

But for Reuben Day, because of the severity of his injury, learning to live with his disability has been difficult and remains a daily struggle.

"When I wake up in the morning and realize that I can't get up without help, sometimes I wonder if it is really worth getting up," Day said. "Once I'm up and on my way, though, I'm fine. That part is behind me and I don't think about it any more."

STANFORD—Modern medical instruments have had a profound impact on the quality of health care, but that impact is not always easy to determine, according to Dr. Allen Ream, assistant professor of anesthesia at Stanford University Medical School.

Analysis of the value of instruments includes often conflicting criteria, says Ream, including need, speed of performance, results in terms of lives saved, and cost.

Future development is coming more and more under the control of government regulations. "Whether this influence becomes a serious impediment to future innovation remains to be seen," he says.

Ream, director of the Institute of Engineering Design in Medicine, made his remarks in the May 26 issue of *Science* magazine.

"The most significant developments in medical instrumentation are improvements in time and scale (instruments tailored to individual needs and locations)," says Ream.

For example, measurement of blood gas concentrations is moving from the laboratory to the bedside, and can be done in minutes instead of hours. This helps decrease economic costs, by making the test more efficient, and non-economic costs, by reducing delay in treatment.

The computer has significantly aided medical care, expecially in diagnosis.

"The modern cardiac catheterization laboratory could not function without it," says Ream. In addition, preprocessing by computer improves the ease and efficiency of monitoring the electrocardiogram (EKG).

Computers also can improve the accuracy and frequency of non-invasive diagnosis, which is more convenient and involves less risk than invasive techniques.

For instance, computer-assisted axial tomography (CAT scanning), by providing more accurate diagnosis, may avoid exploratory brain surgery in some patients.

The promise of computers "is to simplify, not to complicate our professional lives," says Ream.

However, procedures such as CAT scanning have been criticized for the large capital investment they require. (A typical CAT scanner costs over $500,000.)

The greatest costs of CAT scanners are in the data-processing equipment, and these are rapidly decreasing, says Ream. In addition, one study suggests that the costs will be offset by reductions in the use of high-risk and expensive diagnostic procedures.

When use of medical instrumentation increases operating expenses, a hospital can be partially reimbursed for its investment by government or private insurance.

However, instruments, such as a computerized hospital information system which cuts costs, may cause the level of reimbursement from insurance companies to actually drop. It therefore pays the hospital to invest in the more expensive CAT scanner, for example, which garners greater reimbursement

- more -

"The current system of reimbursement to health care facilities rewards the hospital which improves care by increasing definable cost and penalizes the hospital which improves care by reducing operating costs," says Ream.

"Financial incentives must be permitted to encourage applications of instrumentation which may reduce health care costs in an acceptable way."

Another potential impediment to the development of medical instruments is increasing governmental regulation. Medical devices must now be classified and reviewed by the Food and Drug Administration prior to marketing. In addition, California is implementing a law to permit device regulation at the state level.

Concerns about regulation are shared by manufacturers, many of whom are small firms, and by the physicians who use the instruments and contribute to their development.

"Collaborative effort (between manufacturers and physicians) in instrument development is essential," says Ream. "If the device law fosters effective collaboration, it will be an important influence for the good. If it hinders that collaboration, the negative effects will be profound but not immediately evident."

Ream says that as medical instruments change the practice of medicine, previously acceptable evaluation techniques will be inadequate. As a result, new and economically attractive techniques may not be recognized.

"We must be careful to avoid permitting analytic concerns to preclude an effective trial of innovation and application," he says.

STANFORD—Young adults, as well as children, should be sure they are immunized against the "childhood" diseases, says a Stanford pediatrician.

Dr. Ann Yeager, assistant professor of pediatrics, warns that young adults who may not have been immunized as children against diseases such as polio or measles may now be at risk, especially when traveling to other countries.

Speaking on "Childhood Immunizations: Successes and Failures" recently, Dr. Yeager noted that some young people may not have had measles or mumps vaccines, only available in the last decade. They may have "benefited" from the immunizations of others by having less exposure, but if they did not get the disease as children, they are still susceptible.

"We have no natural immunity against the diseases we vaccinate against," says Yeager.

"We are either completely protected or completely susceptible."

Susceptibility is not age-related, she says, but severity of disease is. Many of the childhood diseases, including mumps and measles, are worse in an adult than in a child, and can often complicate existing disorders.

In recent years, measles outbreaks have occurred in junior and senior high schools. Many had never been immunized, or had received the vaccine before they were one year of age or before 1969.

If there is doubt about whether a person has been immunized against measles, Yeager recommends reimmmunization.

Doctors, she said, are particularly watchful for today's college age person who received killed virus vaccines for measles during the early 1960s. Early protection in some of those cases later reversed to create an allergic reaction.

During the last 10 years live measles, mumps, and rubella vaccines are given instead. With these, a small amount of virus is given resulting in a mini-infection without symptoms, which stimulates antibody and protects the person indefinitely.

Vaccine for rubella, formerly called "German" or three-day measles, is the only one given to protect someone else's health, said Yeager, "benefiting future generations and the community as a whole."

Although rubella only causes a mild disease, it can cause severe defects in the fetus if contracted during pregnancy. Since 1972 most children under 12 in California have received rubella vaccine.

Last year the Department of Pediatrics sponsored a mass rubella screening program for girls in three Palo Alto high schools. An average of 25 percent of the 270 juniorb and seniors tested were found to be susceptible to rubella. They were referred to their own physicians for the vaccine.

Yeager also noted that many young people may also have missed the mass immunizations of oral polio vaccine during the early 1960s. She urges them to obtain that protection before traveling outside the U.S.

Since 1972 California law has required that each child entering school be vaccinated against polio, diphtheria, pertussis, tetanus and measles. Immunization against rubella and mumps is also recommended by the State Health Department.

Dr. Yeager's lecture, sponsored by the Stanford University Hospital and Clinics, and by the Department of Pediatrics, was held in conjunction with the national "Immunization Initiative" of the Department of Health, Education and Welfare (HEW) and the American Hospital Association.

HEW has estimated that 40 percent of U.S. children today are not receiving the vaccines available against preventable diseases.

Editors: This news story is released in conjunction with the meeting of the American College of Sports Medicine in Washington, D.C. May 24-27. This story is based on a report to be presented on May 26.

STANFORD—Athletes should have the least exposure to smog as possible just before a competitive event, so their performance won't be impaired, says a Stanford researcher.

Long distance runners, for example, may not have decreased performance during the smoggy conditions if they undergo normal training but limit their exposure on the day of the event.

William M. Savin, formerly of the Human Performance Laboratory, Department of Physical Education at UC-Davis, reported on the effects of air pollution on strenuous exercise at the May 26 meeting of the American College of Sports Medicine in Washington, D.C. Savin is now a research assistant in cardiology at Stanford University School of Medicine.

The study measured exercise performance in ozone levels which would be classified as "alert" or "warning" smog levels. Savin described these as realistic levels, which have been exceeded on some days in Los Angeles.

Ozone is the primary constituent of photochemical smog, produced by the interaction of sun on auto exhausts. The ozone occurring naturally in the upper atmosphere is of a different source.

The study involved nine healthy men who pedaled a stationery bicycle as long as they could while breathing ozone concentrations of zero, .15 or .30 ppm.

The volunteers' mean age was 26, all had extensive athletic backgrounds, and were running competitively or jogging regularly at the time of the study. None smoked.

The men were not aware of the ozone concentration, if any, being administered.

Results show that exposure to as much as .30 ppm ozone during graded exercise resulted in no significant change in performance, although subjects reported symptoms of discomfort more frequently with increased ozone levels.

According to Savin, "The effects of ozone depend upon both the duration and concentration of exposure.

"Well-trained, motivated individuals experience physiologically measurable changes and report symptoms before any change in their duration of performance becomes apparent."

FOR IMMEDIATE RELEASE

STANFORD—

Professor Theodore T. Puck, recognized as one of the "fathers" of research in mammalian cells, will speak on the nature of cancer Thursday, June 1, 1978 at noon at the Fairchild Auditorium of Stanford University School of Medicine.

Puck is director of the Eleanor Roosevelt Institute for Cancer Research and professor of biophysics and genetics at the University of Colorado Medical School, Denver. He is a visiting professor in the department of pharmacology at Stanford this spring.

Puck is well known for developing methods for clonal growth of mammalian cells, and for his studies on the effect of radiation on the genetic material of cells.

His honors include membership in the Institute of Medicine, National Academy of Sciences, the Lasker Award (1958), life-time professorship in the American Cancer Society, and fellowship in the American Academy of Arts and Sciences.

The lecture is sponsored by the department of pharmacology and is open to the public.

STANFORD—R. Gordon Gould, Ph.D., emeritus professor of medicine at Stanford University School of Medicine, died Friday, May 19, of cancer.

Funeral services are private, and a date for memorial services has not yet been set.

Gould, who was 68, was an expert on the metabolism of blood fats and proteins. His major research interests included the regulation of cholesterol synthesis and the role of cholesterol in the development of atherosclerosis.

He found that cholesterol ingested in the diet regulates production and metabolism of the substance by the body. This discovery has widely influenced the development of treatments to prevent atherosclerosis and related disorders.

A native of Chicago, Illinois, Gould, was educated in New York City and received his Ph.D. in organic chemistry from Harvard in 1933. He held teaching and research positions at Harvard, Rockefeller Institute, University of Illinois, and Los Alamos (New Mexico) Scientific Laboratory before coming to Stanford in 1960.

Gould served as director of the clinical chemistry laboratory of Stanford University Hospital until 1969. He was named professor emeritus in 1974, but continued teaching and research activities until shortly before his death.

He is survived by his wife, Edda von Renouf Gould, two children, five grandchildren, and a sister.

Memorial donations should be sent to Stanford University or to the Natural Resources Defense Council, Inc., 122 E. 42nd St., New York, NY, 10017.

STANFORD— Body cooling, hypothermia, is now being used by Stanford University pediatricians to help save drowning victims.

To lower a patient's temperature, the physicians pack the entire body in ice. After the temperature reaches about 31 degrees centigrade, the patient is connected to a respirator and kept under sedation for the next 48 hours.

Placing the patient in a state of restricted animation possibly helps to reduce the risk of brain damage, a common problem in drowning victims, according to Dr. Edward Alderete, chief resident in pediatrics.

The procedure, Alderete said, should be initiated as soon as possible after an accident. Lowering the body temperature reduces tremendously the oxygen demands of the brain thus further helping to prevent permanent brain damage, he asserted.

Alderete believes three patient's lives were saved last year at Stanford through the use of the technique. "They probably would not have gone home at all if we used traditional methods for treating drowning," he added.

Hypothermia for drowning victims has been used now for two years, said Alderete. Physicians began to notice that people who had drowned in cold rivers and lakes revived after prolonged submersions in water. This did not happen if the accident occurred in warm waters.

The hypothermia technique has been used for a long time on parts of the body, such as the heart, during surgical procedures involving adults, said Alderete. Hypothermia, especially "total body" hypothermia, is new to pediatrics and drowning victims.

(Also recently surgeons at the University of California Medical Center in San Francisco reported they had used hypothermia in infants to perform delicate heart surgery).

Alderete said physicians do not know why, but the procedure works better on children than on adult drowning victims.

It may be because "children have a much greater capacity to recuperate from brain injuries than adults," he said.

There are only four or five hospitals in the Bay Area using hypothermia on drowning victims, said Alderete. "The smaller medical centers lack the equipment and staff to perform the procedure. The entire process involves up to five physicians and three or four highly skilled nurses," he said.

Alderete plans to publish a report on the technique this summer based on clinical research performed here at Stanford.

STANFORD— A free public debate dealing with today's medical care issues will be held Monday, May 22, from 1:30 to 3 p.m. in Fairchild Auditorium at Stanford University Medical School.

The debate, sponsored by the Stanford Medical Student Association, will feature four speakers discussing alternative solutions to the problems of equity, quality of care, organization of services and financing.

The speakers include Robert R. Alford, professor of sociology at the University of California in Santa Cruz and author of *Health Care Politics;* Dr. Frank A. Rogers, a Stanford graduate, practicing surgeon in Whittier and former president of the American Association of Physicians and Surgeons; Alain Enthoven, Marriner Eccles Professor of Economics at Stanford Graduate School of Business and special consultant to Joseph Califano, secretary of Health, Education and Welfare, and author of *New Consumer Choice Health Plan;* and Dr. Robert Burnett, former president of the Santa Clara County Medical Society.

The session is actually an extension of a medical school course, "Health Care and Society," taught by Dr. Count Gibson, professor and chairman of the Department of Family, Community and Preventive Medicine at Stanford.

STANFORD—Hospitals providing the most services to their patients and discharging them soonest have the lowest death rates, according to a Stanford study.

Those hospitals providing the least services and keeping their patients longest, have the highest death rates.

In a two-year study, Stanford researchers calculated the expected outcome, length of stay, and intensity of service should be for 600,000 patients, based on the type of disorder and the admission characteristics of the patient. They compared these expected values with the actual values to obtain measures for comparison of hospitals.

"These results, if valid, are of great importance. They have the appeal that goes with the belief that intensive service should yield better care," say researchers from the Stanford Center for Health Care Research in a 650-page report to the National Center for Health Services Research, Department of Health, Education and Welfare.

Authors of the $250,000 study are Dr. William H. Forrest, Jr., director of the Stanford Center for Health Care Research, and Drs. Byron W. Brown, Jr., W. Richard Scott, Wayne Ewy, and Ann Barry Flood, members of the departments of anesthesia, sociology, and family, community and preventive medicine.

The work was an outgrowth of the center's original Study of Institutional Differences in Postoperative Mortality (1974). They concluded in that study that the quality of surgical care in the nation's hospitals varies to such an extent from one hospital to another that it constitutes an important public health problem.

Data for the current study came from abstracted discharge information on 600,000 patients in 17 short-stay hospitals during the four year period 1970 to 1973. These institutions were a stratified random sample from approximately 1300 hospitals that participate in the Commission on Professional and Hospital Activities data system.

Among the patient services studied were diagnostic radiological and clinical laboratory examinations, and such therapeutic services as operations performed, intensive care, drugs prescribed, and blood transfusions. They found substantial differences among hospitals in services provided, even after adjusting for patient populations served.

The team also studied many hospital organizational factors which tested for possible association with the findings concerning services, length of stay and outcome of surgery.

Greater than expected service was associated with larger hospitals, more facilities, high occupancy rates, and several measures of coordination of work at the ward level.

This coordination of patient care activities at the ward level was also associated with shorter lengths of stay and the best outcomes.

Fewer services than expected were correlated with greater experience of the surgeon (years of service) and with tighter control of physicians by the medical staff.

Greater than expected length of stay was associated with high administrative influence, and also with higher hospital costs per patient.

Beyond these findings, Forrest emphasizes the implications of the study's methodology.

"The feasibility of establishing large scale monitoring to evalute the costs and quality of health care in hospitals can be of the greatest importance for national health policy."

STANFORD—"Childhood Immunizations: Successes and Failures" will be the subject of a free public lecture in Fairchild Auditorium on Tuesday, May 23, at 8 p.m.

Speaker will be Dr. Anne Yeager, associate professor of pediatrics at Stanford.

Dr. Yeager authored the principal study in 1976 determining that the best age for measles immunization is 15 months, instead of one year.

The program is being sponsored by the Stanford University Hospital and Clinics, and by the Department of Pediatrics. It is in conjunction with the national "Immunization Initiative" of the Department of Health, Education and Welfare (HEW) and the American Hospital Associaton.

Goal of the national program is to focus on the continuing need for immunizations, the availability of vaccines to prevent childhood diseaes, and the dangers for non-immunized children.

HEW estimates that 40 percent of U.S. children today are not receiving the vaccines available against preventable diseases such as polio, measles, German measles, diphtheria, pertussis (whooping cough), and tetanus.

In studying a large outbreak of measles in Northern California in 1975, Dr. Yeager and her colleagues discovered that a number of children who had been immunized came down with measles anyway. It became apparent that the vaccine was less effective when it was given at the age of one year or younger.

The American Academy of Pediatrics and the U.S. Public Health Service issued new recommendations in 1976 that the immunization be postponed until the age of 15 months.

Dr. Yeager will answer questions from the audience following her talk. Free immunization record cards and fact sheets will be distributed.

STANFORD—"Heart Disease Prevention: A Way of Life" will be the subject of the fourth and last lecture in a series on the heart, to be held Wednesday, May 17 at the Stanford School of Medicine.

The Progress in Medicine lecture will begin at 7:30 p.m. in the Sherman Fairchild Auditorium. The public is invited, and there is no admission charge.

Dr. John W. Farquhar, professor of medicine and director of the Stanford Heart Disease Prevention Program, will discuss high risk factors for heart disease and effective ways of controlling them.

Farquhar directed the Stanford Health Project in Central California, a three-year preventive effort to reduce cardiac risk factors.

Results from that study indicate, says Farquhar, that community-based health education in conjunction with mass media campaigns, can persuade people to change their life style and improve their health status.

That project, he notes, represents the type of preventive effort needed to help stem the epidemic of heart disease which claims the lives of more than 600,000 Americans per year.

The Progress in Medicine lectures are presented as a community service by the dean and faculty of the School of Medicine and members of the Medical Center Council.

STANFORD—

Hyperthermia is being tested as a treatment for superficial skin cancers at Stanford University Medical Center. Hyperthermia is localized heating by high frequency sound waves (ultrasound).

According to Dr. Elaine K. Orenberg-Anderson, senior research associate in the Department of Dermatology, the study is the first time hyperthermia has been applied to these cancers without complementary radiation or drug treatments. Hyperthermia has been used for several years as an experimental treatment for other cancers in animals and humans.

Orenberg is conducting the study with Dr. Eugene Farber, department chairperson, and Dr. David Deneau, assistant professor of dermatology. The research is supported by a one year grant from the American Cancer Society.

"Preliminary results are encouraging," says Farber. Hyperthermia has resulted in shrinkage of tumors in the eight patients treated so far.

"Our ultimate objective is to see if hyperthermia is lethal to these cancer cells," he says. "If it is effective, this technique may provide a painless, non-surgical method of removing skin tumors."

Present treatments of skin cancer include surgical removal and electrodesiccation, a technique in which the tumor is scraped off and the underlying skin is cauterized by a needle. Both treatments leave scars, and are cosmetically undesirable, says Orenberg, particularly if the tumor is located on the face or neck.

The hyperthermia treatments are performed with special ultrasound equipment designed and constructed in the laboratory of Dr. George Hahn, associxte professor of radiology.

Hahn and his associates have found that tumor cells seem to be more sensitive to elevated temperatures than normal cells. Studies in animals and humans have shown that hyperthermia by itself can cause shrinkage in certain cancers, and increase the effectiveness of radiation and drug treatments.

Farber said his group plans to expand their studies and has applied for a second year of funding by the American Cancer Society.

"After the Heart Attack: Rehabilitation" will be the subject of the third in a series of public lectures on the heart to be held Wednesday, May 10 at the Stanford School of Medicine.

The Progress in Medicine lecture will begin at 7:30 p.m. in the Sherman Fairchild Auditorium.

The public is invited, and there is no admission fee.

Dr. Robert F. DeBusk, assistant professor of medicine (cardiology), will discuss present rehabilitation techniques aimed at returning a heart attack victim to normal activities.

DeBusk is director of Stanford's comprehensive cardiac rehabilitation program. The program makes use of exercise testing and training, physical therapy, psychological and dietary counseling.

DeBusk began his rehabilitation program at Stanford in December 1973. He directed one of the first major U.S. studies using exercise testing as soon as three weeks after a heart attack.

A Stanford alumnus (A.B. 1960, M.D. 1964), he served internship and residency at Boston City Hospital, Harvard Medical School.

Dr. John W. Farquhar, professor of medicine, will discuss "Heart Disease Prevention: A Way of Life" at the final lecture in the series on Wednesday, May 17.

The lectures are presented as a community service by the dean and faculty of the School of Medicine and members of the Medical Center Council.

STANFORD—

The review of recombinant DNA research conducted at Stanford University has been criticized for inadequately educating research personnel to the potential hazards of the experiments and for "hampering public involvement" in the review process.

The complaints were raised by a group of citizens at the May 4 meeting of the Administrative Panel on Recombinant DNA Molecules at Stanford. About 50 people attended the meeting.

The panel, which includes members of the university faculty and staff, a student, and a community representative, was set up in 1976 to ensure that all research dealing with recombination of genetic material conforms to safety guidelines established by the National Institutes of Health (NIH).

Attendance at the meetings "has been a very frustrating experience," said Nancy Pfund, research assistant in the Division of Health Services Research at Stanford. Often the policy issues are put off in favor of reviewing research proposals, she said.

Only one meeting in four is open to the public, and even though the minutes of each meeting are supposed to be made available at university libraries, they often were not. The panel was criticed for not supplying minutes to the last four or five meetings.

Several citizens expressed concern that lab personnel who worked near recombinant DNA experiments were not given proper information in handling biohazardous materials.

Diana Dutton, assistant professor of sociology, and community and preventive medicine, suggested that a biohazard task force be created to develop educational and health monitoring programs. As part of health monitoring, regular blood samples could be taken from lab workers and analyzed for exposure to microorganisms.

"I'm not sure what we would analyze if we were to collect sera," said Stanley Cohen, professor of clinical pharmacology and panel member. "We don't know what to monitor for.

"I agree it is important to ensure worker and public safety, but it is also our responsibility not to frighten the public in instances where there is no basis for such fear."

John Kaplan, professor of law, disagreed. "As long as I am on this committee, I am committed by the guidelines to look at this stuff as if it were extremely dangerous."

According to members of the panel, education of technicians and support personnel is being done in several laboratories conducting recombinant DNA research.

The university health and safety office reviews laboratories engaged in recombinant DNA research to enure compliance with the NIH guidelines. As part of the review, safety officers make sure that lab workers are familiar with the research and with the guidelines, said panel member Jack Sidlow, health and safety office manager.

In addition, the panel is preparing a statement to be signed by lab workers indicating their awareness of the research and guidelines.

Presently there is no task force on other biohazardous materials, such as viruses, at Stanford, but according to panel member Pat Devaney, assistant provost, the university committee on research will discuss the possibility of forming one at an open meeting May 19.

Dutton suggested several means of improving public involvement in the review of recombinant DNA research which have been employed at other universities. These included increasing the number of public representatives on the panel, making minutes and other materials more available, and opening every meeting to the public.

The panel response to these suggestions was mixed. John Brauman, professor of chemistry and panel chairperson, apologized for the delay in providing minutes of all the meetings and promised to make them available as soon as possible.

Cohen said that some of the meetings were closed to the public to protect research ideas reviewed by the panel from being stolen. "If the information were not treated as privileged communications, I suspect people would be less complete in what they provided to the committee," he said. "There is a trade off."

However, Burton Richter, professor at the Stanford Linear Accelerator Center, did not feel closed meetings were necessary. In the field of high energy physics, all proposals are made public upon receipt by the review committee, he said. The priority of similar grant proposals is determined simply by the dates stamped on them.

"I think the idea of keeping research ideas secret is totally specious," said Richter. "We should have more open meetings, and I will raise this issue at the next meeting."

The next meeting of the panel, which will be closed to the public, will be set sometime in the next two to four weeks.

STANFORD—

The State Supreme Court will be asked to review whether state capitation grants to private medical schools are constitutional or not.

The Third District Court of Appeal Wednesday (May 3) denied Stanford University's petition for a rehearing on the matter.

That court had ruled unanimously on April 10 that state capitation grants to private medical schools violate the California constitution.

The ruling came in a suit filed by Stanford against the state treasurer and controller to collect $448,800 in capitation support owed to the University for increasing its medical school enrollment.

The appellate court ruling struck down the program run by the State Scholarship and Loan Commission. The program was set up by the California Legislature for the purpose of increasing the number of physicians in the state.

According to John J. Schwartz, University counsel, the University intends to petition the State Supreme Court this month. It is expected that the court will take several weeks to decide whether to accept the petition or not.

In cutting off funds, the state controller claimed that the payments may violate the state constitution which prohibits state support to schools with church ties or to any school not under the exclusive control of the state.

Stanford, which increased its enrollment in 1973 through 1975, argued that bona fide contracts serving important public purposes were not "support" under the terms of the constitution.

ADVANCE FOR P.M. PAPERS THURSDAY, MAY 4, 1978.
EDITORS: This story is released in conjunction with publication in *The New England Journal of Medicine* May 4.
STANFORD—

Interferon, a virus-fighting agent produced by the body, can prevent in cancer patients the spread of herpes zoster, a virus which causes chicken pox and shingles, according to Stanford University Medical Center researchers.

Virus infections are more frequent and severe in cancer patients, because their immune responses have been reduced by the anti-cancer drugs and radiation treatments they receive. Complications arising from these infections can be life-threatening.

In recent studies of infected cancer patients, early administration of interferon "prevented the spread of shingles and promoted healing," says Dr. Thomas C. Merigan, head of the division of infectious diseases. "Treated patients have had fewer complications and less pain than controls."

Merigan and his associates reported their findings in the May 4, 1978 issue of the *New England Journal of Medicine*. The research is supported by a contract from the National Institute of Allergy and Infectious Diseases (NIAID).

Interferon is a protein produced in animals and humans by white blood cells which interferes with the growth of several viruses. In addition to herpes zoster, Merigan and his colleagues have found that interferon can prevent the common cold, specifically, respiratory infections caused by rhinovirus. Interferon also improves the condition of patients with chronic hepatitis B infection.

The protein also stops the growth of tumors in animals, but it is not known if it has a similar anti-cancer effect in humans.

Previously, the Stanford researchers had observed that low blood levels of interferon were associated with the spread of herpes zoster infection (shingles), and that the levels increased during recovery.

"We found interferon only in the very late stages of disease in the tissues that were healing," says Merigan. "We felt that early and continued administration of interferon to increase blood levels might create resistance to the spread of infection."

The study involved 90 cancer patients with herpes zoster virus infection. In three trials, different doses of interferon were given during the first or second day of infection for seven to eight days. Patients were randomly selected to receive the protein or serve as controls.

- more -

The highest dose was most effective. "We found that early treatment with large quantities of interferon is necessary to arrest disease or to block the spread of infection and complications," says Merigan.

Merigan's group is now studying the effect of interferon in controlling chicken pox in children with leukkemia.

According to Dr. Ann Arvin, postdoctoral fellow, children with leukemia are highly susceptible to serious complications of chicken pox. "We're dealing with a life-threatening illness," she says, "which kills close to seven percent of its victims and often involves the lungs, liver or nervous system."

Preliminary studies by Arvin and her associates indicate that interferon may prevent spread of the disease in these patients.

Other infections which may be effectively treated by interferon include rabies, viral infections in newborns, and viral hemorrhagic fevers, says Merigan. Interferon also may be used to prevent the spread of infections in patients who have received organ transplants, he says.

The major obstacle in developing interferon as a medication is the high cost of obtaining it from human white blood cells. The interferon used at Stanford is prepared and purified from white blood cells in a Finnish laboratory and supplied by the NIAID.

So far, chemists have been unable to synthesize, or make the protein from scratch.

As an alternative, the Stanford researchers are testing a virus-fighting drug, adenine arabinoside, in patients with hepatitis B virus and cytomegalovirus (CMV) infections. CMV infections can result in blindness.

Recently, the group reported encouraging results in treating hepatitis B virus infection with the drug.

STANFORD—

A bill which repeals some controversial requirements for the teaching of human sexuality in medical schools has been passed by the State Senate Committee on Business and Professions.

The new legislation would still require that physicians in California receive adequate instruction in human sexuality. But medical school faculties would determine what, how, and who should teach, as they do in all other areas of medical knowledge.

Appearing in support of the measure at the committee hearing April 26 was Dr. Lawrence G. Crowley, deputy dean of the Stanford School of Medicine; Irwin Feinberg, chairman of the statewide committee on academic freedom of the UC Academic Senate; and Alan Goldfein, associate dean of the University of California School of Medicine at San Francisco.

Senate bill 1763 was introduced by Senator John Foran. It passed the committee by a vote of 6 to 1, and is expected to go to the Senate floor soon.

The Foran bill would repeal much of AB 4179, which was sponsored by Assemblyman John Vasconcellos and signed into law in 1976

That law added human sexuality to the list of subjects that physicians must be taught. For the first time it also required the state division of licensing to determine the length and content of the instruction. This was a sharp departure from the practice of faculty determining length and contant of courses, and it brought vigorous opposition from all medical schools in the state.

All the medical schools are supporting the Foran bill.

"We agree that there is a need to provide this kind of instruction," Clayton Rich, dean of the Medical School and vice-president for medical affairs, wrote the committee recently.

"However, rigid and detailed requirements will not ensure effective teaching.... The most effective way to encourage proper education and sensitivity to concerns involving human sexuality is to have the faculty of the medical schools determine the content and design of the curriculum just as they do for the other subjects required for a medical degree," said Rich.

In a statement prepared for the committee, UC officials argued that "State-determined course content could infringe academic freedom to the disadvantage of faculty and students alike.

"What we have here...is a governmental agency, pursuant to legislative direction, designing and dictating virtually every detail of the related educational curriculum. This seems to us an unreasonable precedent for intrusion into the responsibility of educational institutions."

STANFORD[8]

A simple history may be as effective in identifying a patient's gastrointestinal problem as a series of costly x-ray tests, according to a Stanford Medical School study.

After interviewing 483 patients undergoing upper GI tests at a large prepaid health plan and two Veterans Administration hospitals, researchers concluded that the test is often ordered inappropriately, usually does not lead to changes in therapy, and has little relationship to the patients' improvement.

But the study also found that patients place a high value on the tests. Sixty-five percent indicated they very much wanted to have the test. When asked later, 78 percent said the test had allayed their own uncertainty and 51 percent would have requested the test had their physician not ordered it.

Most felt that a large number of tests was the mark of an excellent physician.

These findings were presented May 1 by Drs. Keith I. Marton and Harold C. Sox, Jr., both at the Palo Alto Veterans Administration Hospital, and Dr. J.H. Wasson of White River Junction, Vermont at the joint annual meeting of the Association of American Physicians, the American Society for Clinical Investigation, and the American Federation for Clinical Research, being held in San Francisco.

The patients were men and women aged 9 to 84 from all education and economic levels. Each had seen a doctor because a symptom suggested a GI problem, or an abnormality had been seen on another test or on examination.

Results of the upper GI series showed that in 75 percent of the patients there were either no abnormalities or minor ones. More than 50 percent had normal x-rays. A significant abnormality was revealed in 21 percent.

Many patients said they had the test to look for cancer; but in none of the patients was cancer found.

According to Marton, if a diagnostic test is useful it should be associated with treatment or outcome changes for the patient, or assist in the physician's diagnosis.

But only 7 percent of the patients in the study had their treatment changed as a result of the test. Researchers found no relationship between improvement of symptoms and the results of the x-ray test.

They concluded that more than one-third of the tests were not ordered according to appropriate criteria.

"We determined that the test is not a bad test; we question how it is being used by physicians," says Marton.

The team devised "decision rules" to enable doctors to determine whether the GI series should be ordered for a particular patient. They found that if these criteria were used, there would be a 19 percent decrease in the number of GI tests, allowing a 5 percent error rate in diagnosis.

The rules they established are based on the patient's history: those likely to have abnormalities indicated by the test usually have a history of ulcer, are over 50 years old, have pain that is helped by food or milk, or pain that occurs soon after meals.

Marton intends to examine the effectiveness of other similar diagnostic tests, develop "decision rules" for their use, and then test those rules.

"I hope our study will stimulate others to do similar work," he says. "Our technology is outstripping our ability to use it, and in the meantime it is raising medical costs."

Marton feels that his recommendation for fewer tests will not be hindered by doctors who practice defensive medicine, ordering many tests to avoid malpractice suits.

Litigation, he says, almost never occurs because a physician failed to order a test early enough, if he adequately examined the patient.

"Our goal," says Marton, "is to establish rigorously accurate estimates of the tests' benefit for a particular patient, so the doctor will be comfortable in applying that criteria."

He also points out the patient is able to ask for a particular test if he feels it would be worthwhile, even if the doctor does not.

The authors point out that patient attitudes towards tests may confound attempts at cost controls, and are thus deserving of more careful studies.

In the future, they plan to examine the sources of patients' attitudes, and the role of non-physician factors, such as sex, education level, and age.

STANFORD— Dr. Christian de Rouffignac, a pioneer in studies of renal function, will be guest speaker at the Harris-Kwong Lecture in Nephrology July 6 at 5 p.m. in room M106 of the Stanford University School of Medicine.

Chief of the Renal Physiology Group at The Center for Nuclear Research in Saclay, France, de Rouffignac is visiting Stanford for several weeks. He will speak on renal transport of phosphate.

This subject is of medical interest since the kidney's regulation of phosphate balance may be lost with kidney failure. Loss of phosphate regulation leads to serious bone disease, including wasting away of bone, pain and fractures.

The Harris Lectureship Fund was established in 1976 by Mr. and Mrs. Rachford Harris in memory of their daughter Alexandra. The fund supports visiting scholars at Stanford University who lecture and consult with faculty and students in the Division of Nephrology.

The Sik Lun Kwong Fund was established in their father's memory by his children, and is used to sponsor guest lectures in the field of renal disease and renal physiology at Stanford University Medical School.

The lecture is open to members of the medical community and to the public.

STANFORD— Dr. Rose Payne, a prominent immunologist, and Dr. Norman E. Shumway, a Stanford heart-transplant pioneer, were among six scientists who received awards from the American Tentative Society.

The society, established by the late Associated Press Science Writer Rennie Taylor to encourage independent scientific thinking, presented the $2,5000 awards at a luncheon in New York, June 22.

The society, according to its President Alton Blakeslee, advocates a philosophy which may facilitate quicker acceptance of valid new ideas. "All ideas," Blakeslee said, "should be regarded as tentative. Otherwise we become prisoners of yesterday, stuck with dogmas."

The thinking and careers of Drs. Shumway and Rose Payne "seemed to us and to the advisory committee to exemplify this philosophy," Blakeslee said.

Shumway was honored for his work in the field of heart transplantation. Shumway and his associates were the only team to continue with heart transplants after other surgeons, discouraged by the high postoperative failures, dropped out of the field.

Today at Stanford, because of the progress of controlling rejection and infection, 70 percent of patients survive a year or more, and there is a resurgence of new interest in the procedure in other U.S. centers.

Dr. Payne ranks among a handful of individuals on the international level who are responsible for the discovery of the system of genetic markers in man. These are the antigens which often differ between unrelated individuals and which may provoke a rejection of transplanted organs.

These antigens are used in selelcting indivisuals for transplantation of human organs. They also provide clues for determining which individuals may be susceptible to certain diseases.

Other scientists honored by the Tentative Society included Jocelyn Bell Burnell, who as an astronomer student at Cambridge in 1967 noticed the precisely timed signals from what later were identified as pulsars; Astronomer Frank Drake, who began the first serious quest for extraterrestrial intelligent life; Edwin Land, who invented instant photography; and J. Tuzo Wilson, the Canadian geophysicist who championed continental drift before many of his conservative colleagues would even consider his theories.

STANFORD—Dr. Leland B. Blanchard, leading San Jose physician and longtime advocate of family practice medical care, died Monday, June 26, in San Jose, of an apparent heart attack. He was 66.

The funeral will be held on Thursday, June 29, 10 a.m., at Trinity Episcopal Church, Second and St. John Streets, in San Jose.

A memorial service will be held at Stanford Memorial Church on Thursday, June 29 at 5 p.m.

Clinical associate professor at Stanford School of Medicine, Blanchard had recently been involved in developing the training program for Stanford's new divison of family medicine. He served as associate director of the family medicine preceptorship program, in the Department of Family, Community and Preventive Medicine.

He practiced family medicine in San Jose since receiving his M.D. degree from Stanford in 1937.

He was a charter member and past president of both the Society of Teachers of Family Medicine, and the American Academy of Family Physicians, Santa Clara County chapter.

In 1974 he received the American Academy of Family Physicians' Award of Merit, acknowledging his "outstanding and singular contribution to education for family practice."

Blanchard authored many publications concerning family medicine training for physicians. He served on the Santa Clara County Medical Society's liaison committee to medical schools.

He had long been an active member of the Stanford Medical Alumni Association, serving as its president in 1959 and chairman of the annual fund 1968 to 1970.

He was a member of the staffs of San Jose Hospital, Santa Clara Valley Medical Center, and Alexian Brothers Hospital in San Jose.

Survivors include his wife, Virginia, son Timothy and daughter Sarah, and three grandsons.

EDITORS: Copies of *The Healing Arts* available if not included with story.

STANFORD— Major improvements in the care of heart patients has been made through the use of biotelemetry, according to physicians at Stanford University Medical Center.

Biotelemetry refers to the space-age technology which detects and measures various body functions over distance. Its application to cardiology is discussed in the current issue of *The Healing Arts* magazine, a publication of the Medical Center.

In the coronary surveillance unit, biotelemetry has enabled heart patients to get out of bed more quickly and has speeded their recovery.

The electrocardiograms (EKGs) of these patients are continuously monitored during the first few days after their attack to detect abnormal beats which can lead to a further attack or sudden death.

The EKGs are converted into radio waves by a battery-powered unit which can be worn about the waist, and transmitted to the monitor. This frees the patients of cumbersome electrical cables, and enables them to walk about the halls of the unit.

Exercise, such as walking, is essential to speedy recovery of heart patients, according to Dr. John Schroeder, director of the coronary care unit. Long-term bed rest "can be devastating to the body," he says. "The patient loses strength very rapidly. Blood pools in the veins and can contribute to the formation of blood clots."

The telemetry devices are part of a computerized monitoring system designed by cardiology research associate Bill Sanders and installed in January 1978 by the Hewlett-Packard Corporation of Palo Alto.

Biotelemetry is also used in the care of patients with pacemakers. Regular check-ups are necessary to ensure that the pacemakers are performing adequately.

- more -

However, "the average age of our patients is over 65, and many find it difficult to come long distances to the clinic," says Dr. Jerry Griffin, head of the pacemaker clinic.

These patients transmit their EKGs and pacemaker data over the telephone using a small battery-powered converter. The electrical signals are translated into audible tones, fed into the telephone, and decoded into the EKG printout at the hospital.

Telephone transmission has been used at Stanford for over a year. It has made it easier for physicians to follow the nearly 200 patients who receive pacemakers each year, says Griffin.

In the future, biotelemetry will be used to monitor a wide variety of cardiac functions. Dr. Donald Harison, chief of the division of cardiology, Professor James Meindl, director of the Stanford Electronics Laboratory, and their associates are developing implantable telemetry packages which can measure blood flow, blood pressure, EKG, and pace the heart from specific points in the heart muscle.

These packages, the size of electronic watches, are being used in animal studies to better understand how drugs affect conditions such as conduction failure and heart attack. Eventually, they may improve the treatment by drugs of human heart patients.

Research in biotelemetry is part of a larger effort to improve the detection of life-threatening heart conditions. The majority of deaths due to heart disease (60 percent) occurs suddenly, before patients can be brought to the hospital.

"To save some of these people we must define those with heart disease and abnormal rhythms which are susceptible to sudden death," says Harrison. "Presently we don't have a high enough predictable value."

Editors: Details follow asterisks.

STANFORD—High blood pressure therapy, control of anxiety, inhibition of brain tumor growth and spleen regeneration are among the projects of five scientists recently awarded grant support at Stanford University Medical School.

Funding is from the Biomedical Research Support Grant, sponsored by the National Institutes of Health.

Funds are distributed each year to junior faculty members to assist them in establishing research programs.

Dr. Eric Shooter, chairman of the Department of Neurobiology, heads the committee which selects the grantees. The most recent recipients join seven others announced earlier this year.

The grantees are Drs. A. Crane Charters, acting associate professor of surgery, Frances K. Conley, assistant professor of surgery, David D. Oakes, assistant professor of surgery, Peter Rudd, assistant professor of medicine, and Craig Barr Taylor, acting assistant professor of psychiatry.

* * * * * * *

Charters will be studying the control mechanisms of tissue regeneration in the liver and in the spleen. Information about the controls governing cell division and replication may lead to a fuller understanding of the loss of control over cell growth which occurs in cancer.

Conley will investigate immunological aspects of cancer in the central nervous system. In her studies, she plans to alter the environment of certain immunologic functions in mice. She then will examine the way in which this altered immunologic state allows cells to accumulate around brain tumors, inhibiting their growth. Further knowledge of immunological defenses against brain tumors could lead to methods of preventing their growth in humans.

Oakes will examine the effects of injecting spleen tissue into rats which have had their spleens removed. If spleen function could be restored, protection might be provided against bacterial infection, a major risk following removal of the spleen.

Rudd is developing a simplified daily regimen for patients with high blood pressure. He is studying the possibility of administering the drug propranolol once a day, rather than three or four times a day, the current practice. He hopes to show that the drug's effectiveness is maintained without an increase in side effects.

Taylor is examining alternatives to medication for treatment of general anxiety. He will be comparing the effects of techniques such as relaxation and biofeedback to tranquilizers. Computerized psychological and physiological tests will be given to patients. Results will be based on the outcome of these tests and self-reported changes in anxiety and drug use.

STANFORD—After 18 months of planning, Stanford University Hospital will launch an intensive and broad-based program on July 1 designed to train emergency medicine physician specialists.

The first group to undergo the training is comprised of six resident physicians who were recruited nationally.

"Our objective is to train emergency medical specialists for two main areas," explained Dr. Michael Eliastam, director of the program and director of the Department of Emergency Services at Stanford Hospital.

"These objectives are to provide faculty for other emergency medical training programs, and to train academically-oriented emergency medicine practioners who will serve as the link to their nearest academic medical center."

In addition to actual emergency and intensive care training at Stanford, Eliastam says, the doctors will also receive surgical training at Santa Clara Valley Medical Center in San Jose, and anesthesia, cardiology and psychiatric training at Veterans Administration Hospital in Palo Alto. They will also receive emergency medicine and pediatric training at Kaiser Hospital in Santa Clara.

The physicians will also teach in and be briefed about Stanford's paramedic and moble intensive care programs, and actually ride with trained paramedics on duty.

Furthermore, Eliastam noted, the physicians will participate in department meetings and be trained in administration, reimbursement and billing procedures.

Faculty for the emergency medicine physician training program will be "in-house" at each participating hospital, Eliastam added, with program funding coming from existing hospital funds. No federal funds are being used, he said.

Although there is no current national specialty examination to certify the physicians as emergency medicine specialists Eliastam anticipates such an exam will be in existence by September. Such certification would be made by the American Board of Medical Specialties.

The doctors in the program and their medical schools: Paul David, University of Nebraska, Omaha; Jacob L. Sofsky, Hershey, Pa.; Joan Gates, Texas, San Antonio; Mark Hauswald, California, San Francisco; Robert Hook, Wisconsin; Howard Davis, Pennsylvania.

CITY EDITORS:The following statement was issued by Stanford University Hospital and CRONA (the Committee for Recognition of Nursing Achievements).

STANFORD—

"Negotiations began April 25, 1978, on a new collective bargaining agreement between Stanford University Hospital and CRONA, the professional organization representing the Hospital's non-supervisory registered nurses. The current agreement will expire June 30, 1978.

"In a joint statement released today by the Hospital and CRONA, the community has been apprised that CRONA has served the Hospital and the Federal Mediation and Conciliation Service with the required notice of intent of strike and picket effective 6:45 a.m. on July 2, 1978, if a new agreement has not been reached by that time. In the remaining ten days, numerous negotiation sessions are scheduled. The Hospital is continuing to provide full services to the community and both the Hospital and CRONA have pledged their best efforts to successfully complete negotiations before the July 2 deadline."

STANFORD—A step-by-step behavioral approach for smokers who are trying to "break the habit" has been authored by a Stanford researcher.

Become an Ex-Smoker (Prentice-Hall, Inc., 226 pp., $4.95 paper, $10.95 cloth) by Brian G. Danaher, Ph.D., of Stanford School of Medicine's Heart Disease Prevention Program and Edward Lichtenstein, professor of psychology at the University of Oregon, is intended as a self-help guide and for use in group smoking cessation programs.

"The vast majority of smokers don't attend smoking clinics," Danaher said. "More than 20 million Americans have managed to stop smoking without ever having seen a consultant. One of our goals in writing this book is to provide research-tested skills and strategies that can increase their chances of permanent behavior change."

Designed partly as a workbook with spaces provided for recording personal responses, the volume outlines a series of procedures that have received extensive examination in research and education programs at Stanford University and other centers.

"Old-fashioned personal effort and hard work on the part of the smoker are still needed for the program to be successful," Danaher warns. "The book should be read actively by writing on the work pages and performing suggested tasks."

The program is divided into three phases: preparation, "calling it quits" and remaining an ex-smoker.

The initial phase includes training in how to track personal smoking behavior—smoking urges and number of cigarettes smoked. Deep muscular relaxation techniques that can be used later as a substitute for smoking are also learned.

In the second phase, four different methods for actually stopping all smoking are described. They range from making a personal contract for quitting, to the use of a rapid smoking procedure that can transform the act of smoking into an unpleasant experience.

The final phase in the program includes strategies the novice ex-smoker can use to achieve lasting success.

"Almost everyone continues to experience smoking urges after stopping," says Danaher. "The ability to attack these urges and systematically reduce their frequency and intensity is the key to permanent behavior change."

Alterations in daily routines and the use of substitute behavior and self-rewards may be necessary, Danaher notes.

A resource appendix discusses the use of hypnosis or drugs in smoking cessation, the risks of smoking during pregnancy, smoking and weight gain, and efforts to develop a "safe cigarette."

Innovative smoking control programs in business settings and school health classes are also described. The role of legislation and the health care community in encouraging more widespread smoking control is discussed.

An in-depth review of the research literature on behavioral approaches to smoking cessation is included.

STANFORD—Indiscriminate use of antibiotics is creating serious consequences which may limit their therapeutic value in the future, according to Dr. Jack S. Remington, professor of medicine at Stanford University School of Medicine.

Bacteria that cause serious disease and have gained resistance to antibiotics are one part of the problem. An associated rise in the number of patients who become infected while hospitalized, is equally alarming, says Remington, who is also chief of Allergy, Immunology and Infectious Diseases at the Palo Alto Medical Research Foundation.

Writing in the June issue of *Human Nature*, Remington warns, "unless we can limit the prescribing of antibiotics to their proper uses, we will see increases in the number of antibiotic-resistant bacteria and in the needless suffering and death of patients infected with them."

There are several reasons behind the widespread indiscriminate use of antibiotics, which Remington presents in his article.

- antibiotics are so effective when properly administered, it has taken us many years to recognize their negative possibilities.
- pressure from drug manufacturers, and misleading advertising have contributed to misuse of antibiotics.
- preventive use of antibiotics in hospitals, for patients whose resistance may be lowered or who may be undergoing surgery with risk of infection. Remington believes "there are few circumstances in which prophylactic antibiotics are warranted."
- pressure from patients to receive a prescription after each visit to a doctor.
- lack of supervision, worldwide, which leads Remington to add, "the overuse of antibiotics is a global problem, and by comparison with certain European and South American countries where antibiotics can be bought without a prescription, our controls are stringent."

(more)

Remington cites studies indicating that 100,000 deaths each year may occur in the United States from "hospital-acquired" infections caused by resistant strains of bacteria.

Remington also names several types of bacteria which have developed resistant strains and are "cause for international concern." the diseases caused by these types of bacteria include gonorrhea, typhoid, pneumonia and meningitis.

Once the decision is made to treat a patient with antibiotics, Remington says that proper administration is often haphazard. Choice of the most suitable antibiotic for an individual case may be neglected, for example.

Side effects and allergies related to antibiotics are also increasing, Remington points out, as overuse of antibiotics continues.

There are ways to combat resistant strains of bacteria. Natural antibiotics which are no longer potent may be altered synthetically, regaining their effectiveness against some resistant strains.

Combinations of two or more different types of antibiotics may work against bacteria which have developed resistance to one antibiotic alone.

But these are stopgap methods, and the real need is for closer supervision, Remington says, explaining, "in the past we were able to keep up with the development of bacterial resistance. . . there was always another antibiotic we could produce from organisms in the soil or another chemical modification of an existing antibiotic we could make in order to save lives. . .that time may be drawing to an end."

STANFORD—Blood donor services of the Stanford University Blood Bank will be reactivated at Stanford Hospital in July.

To be available on a mobile basis throughout the Hospital, the new service will enable students, Medical Center employees and staff, patients' families, and members of the community to donate blood in the Medical Center.

The service has not been offered since 1972. At that time, responsibility for blood donations at the Medical Center was temporarily assigned to the Palo Alto subcenter of the Central California Red Cross, while the Hospital's Transfusion Service was expanded to meet specialized compatibility testing and processing needs.

With the reactivation of Stanford's blood donor service, all blood donations at the Medical Center will again be drawn under the Stanford Blood Bank license.

According to Dr. F. Carl Grumet, medical director of both the Red Cross subcenter and the Hospital's Transfusion Service, the new Stanford donor service will supplement blood which the Hospital receives from the Red Cross and Peninsula Memorial Blood Banks. All blood collected in the Hospital will be used for patients at Stanford.

Initially, blood drawing will be done twice a month in the same locations as the Red Cross mobile unit has previously served: in the new Hospital wing lobby, Hoover nurses' cottage, and the medical student lounge, at times that will be announced.

The long-term goal is for more frequent and flexible hours to meet the convenience of staff and visitors, according to Betsy Hafleigh, chief technologist with the Transfusion Service. Increased effort to recruit donors will also be underway in departments throughout the Medical Center.

The expansion of Stanford Blood Bank functions to again include blood drawing will better meet the academic and patient care needs of the Medical Center, says Grumet.

- more -

"This should enhance our capabilities to innovate, implement new ideas, and provide the close, detailed evaluation and monitoring appropriate for blood banking at a major medical center. Such processes are more difficult and cumbersome to perform in either a community or a large national blood program."

For example, Grumet and Hafleigh have collaborated with Dr. Anne Yeager of the Department of Pediatrics to develop and evaluate a reliable screening technique for cytomegalovirus. The virus is transmitted by blood transfusion, and one out of every eight premature babies who have received blood acquire it. A blood test would ensure that only blood from donors who do not carry the virus is used for such infants.

Special lipid-rich blood units are also available from the Transfusion Service for newborns with special needs. An added patient benefit is possible cost savings by using processing reagents developed in the Stanford Blood Bank.

"We want to produce a better product for our patients at no more cost than a community blood bank," says Grumet. As with Red Cross blood, no replacement fee will be charged to patients.

The Hospital's original blood bank and drawing facilities were dedicated in 1966, financed with a gift from the Hospital Auxiliary.

In 1976, new blood transfusion and coagulation laboratories were constructed in the new wing of the Hospital with a $100,000 grant from the William Randolph Hearst Foundation.

Currently, the Transfusion Service handles the second largest volume of blood in California.

Persons who wish to schedule blood donations may call Julie Young in the Transfusion Service, 497-6444. To qualify, donors must be in good health, between the ages of 18 and 66.

STANFORD—"Two hundred miles on a bicycle in a single day!"

That's how the brochure described the "1978 Heart of California Double Century Bicycle Tour," held recently near Davis.

Two intrepid Stanford Medical School students—David Carlisle and David Sartoris—decided that the tour would be "a good diversion from medical school." What they didn't bargain on was having to deal with a few medical problems along the way.

The 200 mile route had to be completed in 24 hours or less, according to the rules of the tour. The registration fee of $10 entitled participants to food and drinks at the nine rest stations, as well as at the lunch stop 100 miles into the ride. Also provided was "sag wagon" backup for those having mechanical difficulties, injuries, and for just plain exhausted riders.

Like many Stanford students, Carlisle and Sartoris ride their bikes to and from the medical school regularly. Neither did much extra training for the event. As Carlisle explained, "We didn't enter it with the idea that it was a race. I just considered it a long bicycle ride."

The pair set out from Stanford at 1 a.m. Saturday, in order to be ready for the start. Sartoris took off first and settled into a steady pace. Carlisle, who started later, began to have trouble with his right knee around the 50-mile point.

"There were several times when we felt like giving up," Sartoris recalled, "but we kept encouraging each other to go on just a bit further."

The lunch stop at the top of Mt. St. Helena was a welcome relief for everyone.

After filling up on such foods as oranges (for the sugar), bananas (to replenish potassium), peanut butter, raisins and lemonade, the riders collapsed on a nearby grassy hill to nap for an hour.

"That was a mistake. I shouldn't have stopped because my knee really stiffened up," Carlisle recalled.

(more)

More than 100 miles in, and a few hills later, Carlisle's knee became too painful and he decided it would be best to stop and hitch a ride back to Davis on the sag wagon.

Sartoris continued on until twlight, and while resting at one of the stops he debated whether to continue on in the darkness. There were 45 miles left, all downhill, and seven hours remaining within the time limit.

Then a messenger arrived at the stop with news that a cyclist had been injured and was lying in the middle of the road. Sartoris went back to help administer first aid until an ambulance arrived.

The injured cyclist had a concussion, and was conscious but incoherent. No one knew if he had been hit by a car, or had just taken the spill on his own.

When the ambulance finally arrived it was 11 p.m. Sartoris was over come with fatigue, and felt shaken up by the accident. He decided to take the sag wagon back to Davis, arriving five hours later.

Taking turns at the wheel, Carlisle and Sartoris drove home, finally returning to Stanford at 8 a.m.

Both cyclists agreed that the experience had been great, but Sartoris isn't sure he will try again next year.

"Now that I know the hills, it would be twice as hard," he explains.

Carlisle feels that next year, with a little more preparation, he will be back in the tour. In addition to enjoying the fresh air and the countryside, Carlisle says, "It was a lot of fun. I like bicycle riding and a ride like this has gotten me back into it."

Sartoris agrees, adding "The greatest part of the ride was the bond of friendship between the two of us."

STANFORD—Dr. Henry S. Kaplan, internationally-known authority in cancer research, has been selected to receive the Lila Gruber Memorial Cancer Research Award.

The award will be presented to Kaplan at the annual meeting of the American Academy of Dermatology, December 4 in San Francisco.

The award and special lectures program was instituted in 1971 by the Lila Gruber Research Foundation under the auspices of the Academy.

Dr. Kaplan, holder of the Maureen Lyles D'Ambrogio professorship in radiology, is director of Stanford's Cancer Biology Research Laboratory.

Both his laboratory and clinical interests have focused on the malignant lymphomas and leukemias. His pioneering radiotherapy techniques have resulted in dramatic gains in the treatment of certain cancers, particularly Hodgkin's disease and other lymphomas.

With his colleagues, Kaplan was responsible for initiation of staging laparotomy with splenectomy in the evaluation of Hodgkin's disease patients.

He also pioneered the use of combined modality therapy, employing both multi-drug combination chemotherapy and total lymphoid radiotherapy for patients with such cancers.

More recently, Kaplan has been involved in establishing permanent cultures of human lymphomas and leukemias and in the isolation of C-type RNA viruses from established cell lines.

Among Kaplan's honors are the 1969 Atoms for Peace Award and election in 1972 to the National Academy of Sciences. In 1977 he was awarded the Leopold Griffuel Prize by the Association for the Development of Cancer Research.

The Gruber award of $5,000 recognizes outstanding contributions in the field of cancer research.

The awards are made possible through a gift of Murray Gruber, in memory of his late wife. Recipients are selected by the Council on Scientific Assembly of the American Academy of Dermatology.

STANFORD—Dr. Kenneth L. Melmon, 43, an internationally known clinical pharmacologist, has been named professor and chairman of the department of medicine at the Stanford University School of Medicine.

His appointment, which culminates an eight-month search, becomes effective September 1, Dr. Clayton Rich, vice-president for medical affairs and dean, announced Friday, June 16.

Melmon will lead the school's largest department, including 12 divisions from cardiology to respiratory medicine. The department has responsibility for the clinical medical training of students, house staff, and postdoctoral fellows at Stanford.

A Stanford undergraduate, Melmon holds the M.D. degree from the University of California Medical School in San Francisco (Class of 1959), and he currently is a professor of medicine and chief of the Division of Clinical Pharmacology there.

"Dr. Melmon has demonstrated exceptional ability as an educator and academic administrator by establishing one of the most highly regarded training programs in clinical pharmacology in the nation," said Rich.

His research has led to 173 publications and to the editorship of the next edition of *The Pharmacological Basis of Therapeutics*, a text book in the field.

Melmon and his co-workers at USCF have recently identified the chemical receptors for histamine on the surface of white blood cells. They also have developed important new concepts concerning relationships between immune and inflammatory processes and their regulation.

He received his residency training in medicine at the University of California Medical Center, and the University of Washington in Seattle, and was a clinical associate in the Experimental Therapeutics Branch of the National Heart and Lung Institute in Bethesda, Md.

Melmon is recognized as one of the founders and leading figures in the field of clinical pharmacology. He was elected president of the American Federation for Research in 1973-74, and president of the American Society of Clinical Investigation for 1978-79.

He is a consultant to the Office of Technology Assessement's committee on generic drugs, U.S. Senate Health Subcommittee, and chairman of the Joint Commission on Prescription Drug Use.

Melmon succeeds Dr. Roy Maffly, professor of medicine, who became acting chairman when the former chief of the department, Dr. Daniel Federman, left to join Harvard Medical School.

STANFORD—Citing "erosion of the moral basis of our profession," a noted physician called on the graduating class of medical students at Stanford University to "transcend the title you have, see through the privileges that come with it automatically" and "reconstruct" a more humanistic foundation for the medical profession.

Speaking during commencement exercises on Sunday, June 18, Dr. Edmund D. Pellegrino, professor of medicine and president and chairman of the board of directors of Yale-New Haven Medical Center, Inc., called on the 94 assembled future doctors to "eradicate the mystique of our words" so that patients may participate with physicians in a "joint decision."

"The gift that you are being given today is a gift that you should return to the patient who comes to you," Pellegrino concluded as a hot sun beat down on 157 graduating students and their families in Grant Courtyard of Stanford University Medical School.

In addition to 94 medical degrees, the medical school awarded 21 Ph.D's, 31 masters' degrees, 10 bachelor of science degrees, and one bachelor of arts degree.

Seven awards honoring excellence in teaching were presented to medical school faculty members.

The recipient of the Arthur L. Bloomfield Award is Dr. Allen B. Barbour, professor of clinical medicine at Stanford. Dr. Barbour was cited for "excellence in the teaching of clinical medicine." He has been named to the Bloomfield Award three times in the past. The Bloomfield award recipient is chosen by the graduating class of medical students at Stanford.

The Henry J. Kaiser Awards were presented to five individuals, also selected by medical students.

Dr. Robert Chase, Emile Holman Professor of Surgery and professor in the Department of Structural Biology, was selected for innovative and outstanding contributions in medical education.

Dr. Norman Blank, professor of radiology, and Dr. Jane A. Morton, physician specialist in pediatrics, were recognized for excellence in clinical teaching.

Dr. Otto A. Mortenson, visiting professor in the Department of Structural Biology, and Dr. Gerald A. Levine, assistant professor of pathology, were named for excellence in preclinical teaching.

The Lucille Daniels Award for Outstanding Contributions to Physical Therapy was presented to Dr. Helen Blood, adjunct professor and director of the Division of Physical Therapy. Dr. Blood was chosen by students in the division's master's degree program.

The diplomas were presented during the ceremonies in Grant Courtyard by Dr. Clayton Rich, dean of the medical school, Dr. Roy Maffly, professor of medicine, and Barbara Kent, acting director of the Division of Pysical Therapy.

STANFORD—Pulmonary embolism, or blockage of blood vessels in the lungs by clots of foreign material, is overdiagnosed and overtreated, especially among women who take oral contraceptives, according to Dr. Eugene D. Robin, professor of medicine and physiology at Stanford University School of Medicine.

Overtreatment by anticoagulant drugs, such as heparin, may have serious side effects, including internal hemorrhaging and even death.

"It is no coincidence that heparin is the most common cause of in-hospital, drug-related deaths in reasonably healthy patients," said Robin.

"In addition, a spurious diagnosis of pulmonary embolism may lead to unwarranted major social and medical consequences in the lives of individual patients," he said.

For instance, women with this condition may be advised against having children or taking oral contraceptives.

Robin made his report in a recent issue of *Annals of Internal Medicine.*

Pulmonary embolism commonly occurs in chronically ill, malnourished and bedridden patients, and in those with congestive heart failure. It has also been related in some studies to the use of oral contraceptives.

The frequency of the disorder among relatively healthy patients, and among women on the pill is unknown, said Robin. But it was assumed to be similar to that of the seriously ill population.

This assumption, compounded by the use of diagnostic procedures which are nonspecific and unreliable, has resulted in overdiagnosis and, consequently, overtreatment of pulmonary embolism.

Most hospitals employ measurement of blood gases, and perfusion and ventilation scanning in diagnosing the disorder.

However, further tests by angiography, or X-rays taken after injecting an opaque dye into the blood stream, are frequently necessary to confirm the presence of the clot in relatively healthy patients, said Robin.

About 80 percent of nearly 1100 patients with suspected pulmonary embolism were shown to be free of clots when tested with angiography during recent studies at several medical centers.

"Had angiograms been unavailable," said Robin, "most of these patients would have been treated for pulmonary embolism."

To prevent overdiagnosis, pulmonary angiography should be made available at hospitals, said Robin. If that is not possible, both physicians and patients should be "aware of the tentative nature of the diagnosis and include an element of uncertainty in planning therapy."

Angiography is not unconditionally correct and has its own problems, said Robin, but it is the most accurate method of diagnosis currently available.

"There are so many elements of uncertaintly in the diagnosis, life history, and management of pulmonary embolism that no universal diagnostic and therapeutic strategy can be currently formulated," he said.

"A searching reexamination of the problem is badly needed for proper patient care."

STANFORD—Persons enrolled in health maintenance organizations (HMOs) have 10 to 40 percent lower medical costs than those with other health insurance, according to a Stanford study.

Most of the cost differences are due to lower hospitalization admission rates, according to Harold S. Luft, Ph.D., assistant professor of health economics at Stanford, writing in a current issue of the *New England Journal of Medicine.*

Luft defines HMO as an organization that has a contractual responsibility to provide health services to a voluntarily enrolled population. Members pay a fixed premium, which is the HMO's major source of revenue.

While confirming that "medical care expenditures are lower for HMO enrollees than for people with conventional insurance," Luft also calls for more detailed studies of how those savings are actually obtained.

In his study, luft found that most of the cost differences are due to hospital admission rates about 30 percent lower than rates of those conventionally insured.

His findings are based on a comprehensive review of studies published between 1951 and 1975, that provide 51 comparisons of HMO enrollees and those in conventional plans.

The differences in expenditure between prepaid and fee-for-service groups seem to reflect differences in practice patterns, according to Luft.

"HMOs typically offer more extensive coverage for ambulatory care, thus increasing demand for these services. If there is a choice between providing care on either an inpatient or outpatient basis, the HMO will probably choose the less costly outpatient mode....

"These findings support the expectation that HMO enrollees receive at least as many or more ambulatory visits as those in conventional plans. They also suggest that HMOs do not save money by reducing ambulatory visits."

Luft found no difference in the average length of hospital stay for HMO enrollees and comparison groups.

He also found that HMOs do not reduce hospital admissions only in discretionary or "unnecessary" categories of care.

"The case in favor of HMOs would be substantially strengthened if it could be shown not only that they reduce utilization of expensive services but also that reduction comes in categories thought to be medically unnecessary." The data, however, suggest lower admission rates across the board.

Because HMOs are receiving renewed interest from policy makers as a method to control medical care expenditures, Luft cautions that until more detailed studies are done to identify how HMOs really obtained their savings, "it is best to move cautiously and carefully to separate rhetoric from evidence."

STANFORD—Extensive efforts are underway to make Stanford University Hospital more accessible to disabled persons, according to hospital officials.

These activities are part of a continuing university-wide program to aid disabled students, visitors and employees.

According to hospital planner and architect Richard Pierce, $37,000 has been spent during the last two years to make restrooms, ramps and telephones in the hospital easier to use by deaf and blind persons, and those confined to wheelchairs.

Restrooms in the clinic areas (Boswell and Edwards buildings) have been fitted with free swinging doors, and stalls and fixtures have been modified to permit easier access by persons in wheelchairs.

Ramps have been placed from sidewalks to the street. Telephones have been lowered, and extra volume controls have been installed for deaf persons.

The hospital has received bids for installation of automatic doors in the rear of the clinic, and is now waiting for budget approval before beginning construction.

Other changes are being investigated, including lowering drinking fountains, lowering buttons in the elevators and installing braille numbering on the elevator panels.

In addition to changes in hospital facilities, the personnel department is actively soliciting suggestions for improving the working conditions of disabled employees.

All applicants for jobs in the hospital are asked to indicate voluntarily whether they consider themselves disabled, and what special accommodations they may require. Similar questionnaires will be sent to all current employees in the near future, according to employment manager Joseph Breen.

The personnel department consults with Bay Area organizations representing the disabled, and will hold public meetings in the future to involve disabled employees in evaluating the employment situation, says Breen.

Modifications in facilities and employment conditions are being made in accordance with the requirements of sections 503 and 504 of the Rehabilitation Act of 1973, which prohibit institutions receiving federal funds and contracts from discriminating against disabled persons.

Efforts to expose physicians to the needs of the disabled also are underway at the medical school. The department of family, community and preventive medicine sponsors a course on medical and community aspects of spinal cord injury.

Now in its fifth year, the course allows medical students to leave the lecture hall and interact with disabled patients on a social as well as clinical level.

STANFORD—A hiring freeze on personnnel in the Stanford University School of Medicine and the Stanford University Clinics has been ordered by Dr. Clayton Rich, effective immediately.

The problem, according to the vice-president for medical affairs and dean of the school, is that clinic expenses have been rising much faster than income.

In a letter to the faculty, Rich explained: "No commitments are to be made for new positions or replacement of faculty or other physicians, including house staff and fellows, who are paid in whole or in part from clinic funds."

The freeze applies to both the medical school and the clinic because the budgets of the two units are related. Besides faculty, it covers all personnel in administrative service departments. The freeze will remain in effect until the budgets and the programs of each clinic operation are reviewed, he said.

Rich also announced that he is appointing an Advisory Committee on Programs and Resources "to advise me on those steps that must be taken now and in the future to assure financial equilibrium...and to maintain the essential academic strengths of the school."

"Each clinic operation and supporting administrative program will be examined," Rich said. "This is for the purpose of developing a plan for fiscal 1978 and beyond that meets the academic and financial needs of the school.

"Once the review for each department has been achieved, the freeze will be lifted and that department can proceed along the lines of the established plan."

Rich said that if vacancies must be filled to avoid disruption in certain operations, special clearance can be obtained from appropriate administrators.

The projected clinic revenue next year is expected to go up 2 percent, but expenses will increase 16 percent, according to estimates. The planned clinic budget for the next year is $19 million.

"The present trends will cause a deficit in the clinic operation in a couple of years unless steps are taken now to reduce expenses," Rich said.

- more -

Rich explained that it is not feasible to support clinic deficits with medical school general funds. "The school's budget is under great pressure already and has been maintained only because of a number of steps taken early in spring," he said.

The medical School has reduced its operating budget by more than $700,000 in a series of projected cuts to prevent a deficit next year.

"It is necessary to restructure the clinic operation so as to preserve its most important teaching services, but also maintain its financial integrity," Rich said.

Besides cost reductions, the dean said he anticipates involving faculty in the development of long-range plans to build up new clinical programs where academic needs exist, and there is an opportunity for expansion.

Rich attributed the fiscal difficulties in part to a reduction nationally in the number of office visits and hospital admissions, which affect both doctors in private practice and academic medical centers.

"This, coupled with tight price controls and regulations affecting payment for medical services, are forcing major changes in the operation of academic centers," he said.

"It's critical that those measures we are taking to reduce expense be selected in such a way that the school's fundamental qualities of excellence in education and research are preserved," Rich said.

Stanford University Clinics are a teaching unit of the medical school. Staffed by faculty members and assisted by resident physicians and advanced students, they provide outpatient services in more than 60 specialties and subspecialties.

The faculty practice involved 85,000 patient days of hospitalization and 135,000 outpatient visits last year. The professional service income of the faculty comprises 39 percent of the medical school's budget, excluding sponsored research and plant improvements.

STANFORD—Paul Berg, Willson professor of biochemistry at Stanford University School of Medicine, has been selected as one of four recipients of the newly-established Sarasota Medical Awards.

The other recipients include Eugene Braunwald, professor of medicine at Harvard Medical School, Robert A. Good, president and director of the Sloan-Kettering Institute for Cancer Research, and Nobel laureate Rosalyn Yalow, chief of Nuclear Research Studies at the Veterans Administration Hospital, Bronx, New York.

The awards, which include a specially-designed medallion and $10,000 for each recipient, will be presented at the first Sarasota Medical Awards Conference in Sarasota, Florida, April 1979. All four recipients will present papers at the conference.

Sponsored by the Sarasota Memorial Hospital Foundation, the conference and awards are designed "to recognize extraordinary achievement in all areas of medicine and related fields, and to provide a forum for outstanding individuals in these fields," said Harlow J. Heneman, chairman of the board of the Foundation.

Award winners were selected by a panel of Florida physicians, including the deans of the three Florida medical schools.

Berg has made important contributions to the understanding of how living cells make proteins.

Proteins are long chains composed of chemical units called amino acids. Berg found that certain enzymes were responsible for activating specific amino acids and for insuring that they were assembled in the proper sequence for the formation of a particular protein.

This work earned Berg the Eli Lilly Award in Biochemistry in 1959, and the California Scientist of the Year Award for 1963. In 1972, he was designated Harvey Lecturer and awarded the V.D. Mattia Prize of the Roche Institute.

Berg is a member of the American Academy of Arts and Sciences, the National Academy of Sciences and Institute of Medicine, the American Society of Bacteriologists, and former president of the American Society of Biological Chemists.

A native of New York City, Berg did his undergraduate work at Pennsylvania State University, and received his doctorate in biochemistry from Western Reserve University in 1952. This year he received the honorary doctor of science degree from the University of Rochester and Yale University.

He taught at Washington University in St. Louis before coming to Stanford in 1959. He served as chairman of the department of biochemistry at Stanford from 1969-1974. His reputation as an excellant teacher earned him the Henry J. Kaiser Award in 1969 and 1972.

Berg is noted also for his research involving recombinant DNA, the so-called gene-splicing experiments. He was one of the first scientists to raise questions about the potential dangers of the experiments in 1971. He headed the National Academy of Science committee which called for a temporary halt of certain experiments until their potential risks were analyzed.

STANFORD—A new training program in cancer biology will be offered to graduate and postdoctoral students at Stanford University this fall.

Supported by a $1.5 million grant from the National Cancer Institute for the first five years, the program is a unique attempt to provide training in and improve collaboration between different cancer-related fields, says program director Robert F. Kallman.

The interactions of specialists working as a medical team has made great strides in the treatment of certain cancers, such as Hodgkin's disease and leukemia.

For instance, the treatment of Hodgkin's disease represents the combined expertise of cancer biologists, diagnostic radiologists, surgeons, pathologists, radiotherapists and medical oncologists.

Kallman believes this cooperative effort can be enhanced if the specialists receive training in the other disciplines.

"We're not trying to make a jack-of-all-trades," says Kallman. "We're trying to get cross-fertilization across a number of different fields."

Presently, 34 faculty members from several departments in the schools of medicine and humanities and sciences are participating in the program.

They include Merton Bernfield, professor of pediatrics and chairman of the Human Biology Program, Stanley Cohen, professor of medicine and pioneer in recombinant DNA research; Errol Friedberg, associate professor of pathology; George Hahn, assistant professor of radiology and well-known researcher of hyperthermia; Philip C. Hanawalt, professor of biological sciences; Kallman, who also directs the division of radiobiology; Henry S. Kaplan, D'Ambrogio Professor of Radiology and director of the Cancer Biology Research Laboratory; Tag Mansour, chairman of the department of pharmacology; and Eric Shooter, chairman of the department of neurobiology and well-known researcher of nerve growth factor.

The program is open to students wishing to pursue a doctorate degree in cancer biology, and to qualified medical students desiring a combined degree.

Students may apply to do research under one of the participating faculty members. In addition, a special course in cancer biology will be offered starting in the winter quarter.

More complete information about the program and procedures for admissions can be obtained from Kallman and from the other faculty members.

STANFORD— Joan Mersch, this year's recipient of the annual Dr. Thomas A. Gonda Employee-of-the-Year Award at Stanford University Hospital, sees nursing as a multifaceted profession. Mersch believes that nurses should provide their patients with more than technically proficient care.

"You need a warm, caring human being as well as a dextrous technician," she says.

Mersch was presented with the award by Gary Mecklenburg, director of the hospital, capping the annual awards banquet held recently at Rickey's Hyatt House in Palo Alto.

As clinical nursing coordinator in the coronary care unit of Stanford University Hospital, Mersch comes into contact with critically ill patients who may be confronting the possibility of death for the first time and, often, they are reassessing their priorities in life.

"Sensitivity to the patient's expressions about death is very important," she says, and an empathetic nurse can help a patient towards spiritual recovery as well as physical recovery.

Mersch feels that nurturing plays a large role in nursing and the personal contact is an essential part of treatment.

"You can't establish a therapeutic relationship if you don't get to know people," she adds.

Mersch believes that the stresses of daily life and the pressures of "getting ahead" contribute to many health problems today. Recognizing this stress, she feels, is an initial step towards a healthier lifestyle.

For this reason, she finds it gratifying to watch a patient make the decision to ease up on external commitments. In particular, she recalls one young man, highly respected in the business community, with children still in grade school, who made the decision to slow down in his career. "I want to see my youngest graduate from high school," he told her.

However, a nurse must also be sensitive to the fact that some people wouldn't be happy altering their way of life, and, according to Mersch, this decision from a patient is more difficult to accept.

- more -

Mersch did her undergraduate work at the College of St. Teresa in Winona, Minnesota, and gained clinical experience in Rochester, Minnesota. She has worked in Denver at the University of Colorado Medical Center as a staff nurse and as a head nurse, and she received her graduate degree from the University of Colorado.

Mersch came to Stanford in the fall of 1971. She worked for one year on a medical surgical unit before joining the coronary care unit and cardiac surveillance area, where she is now responsible for patient care around the clock.

Mersch says she likes to think that the Gonda Award was not given to her as an indvidual, but was meant for her staff.

"Perhaps I represent nursing services," she says, "and we were given the award. I like to think of it that way."

After work, Mersch follows her own advice and enjoys running to help reduce some of the stress built up during the day. She runs four days a week and plays tennis on weekends.

One change she hopes to see at Stanford is the establishment of a college of nursing.

The Gonda Award was established in 1975 in honor of Dr. Thomas A. Gonda, former director of Stanford Hospital and now chairman of the Department of Psychiatry and Behavioral Sciences in the School of Medicine at Stanford.

EDITORS: Copies of *The Stanford Magazine* available if not included with story.

STANFORD—In the world of television, bionics is associated with superhuman strength and speed, telescopic vision, and easily replaceable body parts.

In the real world, bionics means helping people who have been crippled, injured or disfigured by disease or accident to attain fairly normal physical appearances and functions. Bionics is the science which designs instruments and systems modeled after living organisms.

Physicians at Stanford University Medical Center employ bionics to replace crippled hip joints and reconstruct facial and other body defects. They are currently testing an electronic hearing aid and a circulatory assist device which may help save dying hearts.

These projects are described in an article in the current issue of *The Stanford Magazine*, a publication of the Stanford Alumni Association.

— — —

A boy who was born without thumbs undergoes surgery to move his index finger to the thumb position. Now he can grasp objects.

A breast removed because of cancer is restored with a lump of silastic, a silicon rubber material, implanted under the skin. A new nipple is formed from skin and cartilage grafts taken from the ear. The reconstructed breast looks remarkably like the natural one.

The son of a famous millionaire has his ear taken off by kidnappers. A piece of cartilage taken from his ribs, sculptured, and placed under the skin restores the ear to its former likeness.

These are examples of operations performed at Stanford's division of plastic and reconstructive surgery to correct disfigurements caused by birth, disease or injury.

Many of the reconstructions are made possible by microsurgery, the use of tiny instruments, suture materials and a microscope to repair nerves, blood vessels and tendons.

In the future, artificial hands operated by nerves in the forearms may be able to detect temperature and touch, says Dr. Robert Chase, Emile Holman Professor of Surgery. And it may become possible to transplant entire limbs from one person to another. "The technology is here," says Chase. "The only problem is rejection of transplanted tissues by the body."

—more—

Arthritis afflicts 20 million persons in the United States, causing pain, crippling joints, and sometimes resulting in death. Although there is no cure for the disease, drugs are now available to relieve the pain and stiffness, and artificial parts can restore function to crippled joints.

Stanford is a major center for hip joint replacement. Since 1971, nearly 450 total hips have been replaced with artificial ones at the Hip Clinic. The new hips consist of spherical plastic sockets fitted with stainless steel ball joints. These are attached to the skeleton with bone cement during surgery.

There is some problem with infection, but most patients have responded well to the surgery, and have recovered essentially full use of their hips, says Dr. David S. Burton, Hip Clinic director.

The joints show little evidence of wear even five years after replacement, says Burton. Hip joint replacement previously was performed only in persons over 60, but today the longer-wearing parts are placed in children who can't move their hips because of rheumatoid arthritis.

Artificial parts to replace other joints such as knees, elbows, wrists and shoulders are now being developed.

— — —

Electronics is being investigated at Stanford as a means of overcoming acquired deafness, that which occurred because of injury, illness, or other trauma.

Dr. Blair Simmons, director of the division of otolaryngology, and Professor Robert White, vice-chairman of the Department of Electrical Engineering have been collaborating for over 10 years in the development of a tiny electrical package which can be implanted behind the ear.

Sound picked up by the package is converted into electrical impulses and transmitted to the auditory nerve, bypassing damaged portions of the ear.

The device can transmit frequencies of sound between 50 and 600 cycles per second. This is only a small part of the range used in human speech (300-3,000 cycles per second), but is in the range required for meaningful communication between partially deaf children.

"The sounds provided through the implant are not high fidelity, but they are functional," says Simmons. "They will enable people to talk and to distinguish the beat of music."

The success of the implant depends on the ability of the hearer to recognize what is being sent through the electrodes. For this reason, only persons who lost their hearing after they learned to speak are being tested with the implant.

In two volunteers recently implanted, the device has improved their ability to read lips and recognize simple tunes. Further work is necesary, says Simmons, before the device will be an effective conversation aid.

— — —

—more—

Electronics also may provide a means of circulatory assistance which is stronger and can be used longer than any current technology.

Artificial heart assistance refers to devices outside of the heart which aid in the pumping function. These include the heart-lung machine used during open-heart surgery, the intra-aortic balloon pump which helps weak hearts recover from failure or surgery, and left-ventricular assist devices.

Of these, only the last device can provide the long-term circulatory support needed by the many patients who now die of pump failure.

The left-ventricular assist device draws blood from the left ventricle and pumps it into the aorta to maintain the circulation. Most of the present models are powered by a compressed air source located outside the body. However, this arrangement restricts patient mobility, and allows the possibility of infection through the external connections.

Stanford researchers and Andros, Inc. of Berkeley are developing a left ventricular assist device powered by electricity. Electrical energy will be transmitted through the skin to the internal pump by induction coils, thus eliminating the need for external connections.

The device has been tested at Stanford only in calves for periods as long as six weeks. According to Dr. Philip Oyer, assistant professor of cardiovascular surgery, it will not be ready for clinical testing in humans for at least two years.

"Initially," says Oyer, "the device would be used after heart surgery to aid only those patients who can't be separated from the heart-lung machine because their hearts are to weak to support circulation.

"If it is successful in these patients, the device may then be used in others who can't be helped by any other surgical or medical treatment. And, at Stanford at least, it may buy time for those patients who are waiting for a heart transplant."

STANFORD—Dr. Hugh O. McDevitt, professor of medicine in the division of immunology at Stanford University School of Medicine, has been appointed to the National Advisory Allergy and Infectious Diseases Council.

The council is the primary advisory body for the National Institute of Allergy and Infectious Diseases. McDevitt's appointment is effective through 1981.

McDevitt, 47, is well-known for his pioneering work on the genetic controls of the immune response. His group discovered that the genes controlling the ability of the body to respond to foreign materials are clustered together on one chromosome in the mouse, and are closely linked to the genes responsible for the transplant rejection reaction.

A native of Cincinnati, Ohio, McDevitt obtained a bachelor's degree with honors from Stanford (1952) and his doctorate in medicine degree from Harvard Medical School (1955). He taught bacteriology and immunology at Harvard before coming to Stanford in 1966.

His many honors include election to the National Academy of Sciences and the 1977 Borden Award for outstanding research from the Association of American Medical Colleges.

CITY DESKS: Picnic photos available on request if not included with story.

STANFORD—A picnic may seem like an unusual addition to a course at Stanford Medical School, but this picnic was special.

A group of medical students here invited a dozen severely disabled students from Berkeley to the outdoor event, as the windup to a course offered by Dr. David Kaplan of the Department of Family, Community and Preventive Medicine and Dr. Sheldon Berrol, acting director of the rehabilitation program at Santa Clara Valley Medical Center.

The course, "Spinal Cord Injury: Medical and Community Aspects," consists of a one-day field trip to several spinal cord injury rehabilitation programs in the Bay Area.

Designed to expose Stanford medical students to the medical and social problems of the severely disabled, the course was started five years ago, and is offered each quarter during the school year. It is a popular course, accommodating about fifteen medical students every quarter.

According to Kaplan, "What happens when medical students take the course is a turnaround in their attitude toward severe disability, from tragedy to optimism."

The picnic idea came up during a follow-up session to the course when the students were discussing their experiences from the long, intense day.

In the morning, the class traveled to Santa Clara Valley Medical Center, which houses the largest spinal cord injury rehabilitation program in Northern California, according to Berrol, acting director of the program. He introduced the program goals, telling the students, "The concepts of independence for the disabled are different from what they used to be. The goal of the acute care program is to maximize residual function."

As patients progress, Berrol explained, they are encouraged to return to a productive, independent life. This may take several years, with medical supervision and counseling. Among the social difficulties facing the handicapped are family reintegration, sexuality, and vocational problems.

Next, the class traveled to Berkeley, making their first stop at the Center for Independent Living (CIL), an organization which provides services and training to disabled individuals, emphasizing self-sufficiency. CIL offers services such as wheelchair repair training, computer training, attendant referral, legal counseling, transportation and housing assistance.

During their discussions at CIL, the medical students heard that the attitude among the handicapped towards the medical profession is not altogether positive. Later, one medical student commented, "The experience was both jarring and frustrating. Jarring not because of what I saw, but because of the reception we received as future physicians. The people we talked to literally pelted us with complaints of lack of understanding and inadequate care administered by members of the health profession."

Berrol had commented earlier in the day, saying "Most health professionals have not been exposed to the severely disabled and are frightened by them." This lack of exposure and lack of understanding often results in inadequate care and an insensitivity toward disabled patients, according to Berrol.

- more -

Expressing frustration at "this gap in our medical education," most of the medical students felt that the course had provided an opportunity for positive exchange.

The final stop of the day was a dormitory where disabled students live together with able-bodied students. This residence program is part of the Physically Disabled Students Program at the University of California.

Sue O'Hara, coordinator of the residence program, summarized its purpose, saying, "Our goal is to set up the minimum structure to facilitate independence." As students become less dependent, they are encouraged to move out and find accessible houses or apartments near the campus.

The Stanford medical students were guests at a dinner hosted by the Berkeley students.

According to Karen Collins, a first-year medical student, "Being able to sit side by side and just chat with our hosts and hostesses was the best part of the day."

Karen Collins, Bill Quick, and several other students decided to reciprocate the hospitality they received at Berkeley by inviting the disabled students to Stanford. Anna Maria Storniolo, another first-year student, expressed her gratitude by saying "This was my first exposure to people with such severe physical disabilities, and I was bursting with questions. I really appreciated the candor with which all of our questions--even the most personal--were answered."

It was warm and breezy when the vans from Berkeley pulled into parking spaces reserved for the handicapped, next to the Fairchild Building at Stanford.

Quickly renewing acquaintances, the group enjoyed a lunch on the lawn, a feast of cheese and meat sandwiches, potato salad, fresh deviled eggs, cake and strawberries.

"It's the first time so many of us have been together outdoors," noted Sue O'Hara, coordinator of the residence program.

Everyone was interested in seeing the Stanford campus, so the group later embarked on a tour, a fleet of wheelchairs and walkers moving across campus.

"They introduced us to the importance of their chair," Karen commented. With the help of the wheelchairs, the group was able to travel several miles around campus. A few obstacles were encountered along the way, although the route had been carefully planned.

Soon after leaving the medical school, the group discovered a dead-end sidewalk, without a ramp leading down to the street. By backtracking one block, this obstacle was bypassed. Many of the inaccessible buildings had to be viewed from outside.

Along the way, conversation was varied. Someone commented on the fact that the premiere of a new film, "Coming Home," took place in a theater inaccessible to wheelchairs. The film is about a quadriplegic Vietnam war veteran.

Mary Ann Hiserman, a second-year graduate student in architecture at Berkeley, took many photographs of the campus. Built into her wheelchair is a special tripod attachement for her camera.

Upon arrival back at Fairchild Auditorium, the group enjoyed cooling drinks before the Berkeley students had to depart. The picnic had been a success.

One medical student who wrote an evaluation of the course, managed to sum up the feelings shared by all the participants at Stanford. She said, "I realized that, without being aware of it, I'd always dealt with severely disabled persons on less then a one-to-one level. Instead I was either condescending or too uncomfortable to carry on the same kind of conversationn that I do with able-bodied persons.

"The experience of conversing with--and especially of learning from-- these people was invaluable. This won't be fully appreciated until I begin to interact with disabled people in my professional career."

STANFORD -- A new blood fat analyzer for premature infants has been given to Stanford University Hospital by the Palo Alto-Menlo Park Soroptimist Club.

Dr. Philip Sunshine, professor of pediatrics and director of the Premature Infant Research Center, received a check for $1200 to cover the costs of the device May 23 from Soroptimist Club members Mary Phares, Mary Esther Cander, and Mrs. Robert Rose.

According to Sunshine, the analyzer will be used to monitor levels of triglycerides (fats) given intravenously to low birth weight and premature infants.

Fat is a high energy fuel which is added to the glucose and protein diets of these tiny infants in many centers throughout the country.

However, little is known about the ability of the infants to metabolize, or use fats. Inefficient use will result in high levels of fats in the blood. This can be avoided by careful monitoring.

The new device makes it possible to determine fat levels from a drop of blood in minutes without leaving the infant's bedside. Alternate methods may require hours of laboratory work and large quantities of serum.

Improved monitoring will help investigators plan the best diet for underweight infants, said Sunshine, one that is rich in nutrients, and at the same time easy for their bodies to use.

STANFORD -- Research in pediatric cardiology at Stanford University Medical Center has been supported for the third straight year with a gift of $1700 from the Palo Alto alumnae chapter of the Alpha Phi sorority.

The money will be used to continue animal studies of the effects of oxygen deficiency on fat and carbohydrate metabolism.

"These studies have important implications for children with heart defects which result in oxygen deficiency," says Dr. David Baum, chief of the division of pediatric cardiology. Disruption of metabolism, the processes by which energy is provided to the body, can affect growth, impair temperature regulation, and lower the activity level of these children, he says.

So far, Baum has found that lowered oxygen levels in the blood suppress the release of insulin, a hormone which promotes uptake of sugar by body tissues.

The drop in insulin increases blood levels of sugar, and makes more of it available to the brain, which is primarily dependent on this fuel. This may help protect the brain during the period of oxygen shortage, says Baum.

The Alpha Phi sorority supports cardiology research nationwide. In the last two years, the local chapter has supported the study of ventilation and adipose (fat) tissue in pediatric cardiology at Stanford. The money is raised through the group's annual lollipop sale.

STANFORD—

Astronauts who spend a long time in space may suffer skeletal weakening similar to the effects of old age or long-term confinement to bed, according to researchers at National Aeronautics and Space Administration (NASA).

This phenomenon, called osteoporosis, has caused concern among scientists and physicians because weakened bones break easily and take a long time to heal. Also, there is no effective remedy for the condition.

Engineers and physicians at Stanford University and NASA's Ames Research Center in Mountain View are studying the disorder in an attempt to provide better means of diagnosis and treatment.

Experiments conducted at Ames have shown that healthy humans confined to bed and experimental animals restrained in a sitting position for several weeks lose minerals such as calcium from their bones.

"We have found in these studies that dietary calcium supplements will not stop the loss of bone mineral," says Dr. Don Young, NASA physiologist at Ames. Vigorous exercise and high calcium diets also did not arrest the loss of mineral from the bones of astronauts on the last Skylab mission, he says. That voyage lasted 84 days.

It is not known why osteoporosis occurs during long periods of inactivity or weightlessness, says Young, but the phenomenon may be related to the reduced weight bearing and stress placed on the skeletal system.

"These studies suggest that the loss of bone minerals is one of the major limiting factors for long-term space flight," he says.

Young and Professor Charles Steele of the department of aeronautics and astronautics at Stanford University are testing a new technique which measures bone strength in patients at Stanford Hospital's orthopedic surgery clinic.

The technique involves measuring the bending stiffness of bone in response to an applied vibrational force. Stiffness is related to the integrity and strength of the bone.

"Preliminary results are very exciting," says Steele. In the 50 persons tested so far, there is a good correlation between bone stiffness and a subjective evaluation of physical condition. Strong and healthy persons tend to have high stiffness values, whereas injured or ill persons tend to have low values.

"The technique is expected to provide a quantitative measure of bone health, and a non-invasive diagnosis of osteoporosis," says Dr. Donald Nagel, chief of orthopedic surgery at Stanford. Other diagnostic methods include biopsy, or removing bone fragments for examination under the microscope, and X-rays.

In addition to diagnosing osteoporosis, the vibrational technique may aid in testing methods of treating the disorder, says Nagel.

One experimental treatment involves electrical stimulation of bone by placing it in an electromagnetic field.

It is known that when an electrical current is induced in bone with electrodes, bone material will move from one electrode to the other, similar to the way a battery works.

Researchers are now trying to produce the same effect by placing bone in electromagnetic fields. Dr. Andrew Bassett of Columbia College of Physicians and Surgeons in New York has reported that 85 percent of fractures which had not healed within eight months of breakage healed with electrical stimulation.

Nagel recently began testing this treatment on patients at the Stanford orthopedic surgery clinic.

STANFORD—The major obstacle to reducing illness throughout the world is not a lack of medical knowledge about diseases, but the difficulties in applying it within the constraints of environment, culture, economics and politics, according to a new book by Dr. Paul F. Basch, associate professor of family, community and preventive medicine at Stanford University School of Medicine.

An authority on tropical diseases, Basch recently published an extensive examination of the world health field entitled *International Health* (1978, Oxford University Press).

Half of the world's population has no access to health care, and millions die each year of readily preventable sickness, quotes Basch from a 1976 testimony to the U.S. House of Representatives.

The greatest portion of people in developing countries live in rural areas, yet most of the medical care, including physicians, is provided in the cities.

"Known scientific and technical advances are seen to have no beneficial impact on the lives of most people," says Basch.

The inequity of medical services and the dearth of primary care supplied on an international level are due in part to political and economic conditions, but these can be overcome.

Basch points out that the "barefoot doctor" of the People's Republic of China has helped to improve health conditions without massive infusions of money or sophisticated technology.

"Perhaps the most important lesson to be learned from China is that it is not impossible for a poor country to mount successful efforts against the most pervasive and damaging threats to health, that large amounts of money or of medical research are not necessarily prerequisites, and that lack of either should not be accepted as justification for official inaction," he says.

-more-

Success on the international level requires an understanding of the circumstances that lead to disease and death in each country, including local environment, genetics, culture and behavior.

For instance, stomach cancer is relatively common in Japan, but rare in the United States. The incidence of the disease decreases among Japanese immigrants to the U.S., and, among their American-born children, it resembles that of Caucasian-Americans. This suggests that dietary or environmental factors may play a role in the development of that cancer.

Comparative studies of how diseases are represented in different countries provide important information about their cause and development, and aid in prevention efforts.

However, a major block to health care planning is simply inadequate information. In many areas of the world, for instance, even basic census data are lacking.

International health care workers not only must take into account all the variables, but avoid "cultural blind spots", the assumption that what works in one country will work in another.

A dramatic example of this is the introduction of bottle feeding into developing countries. As a result, many women have stopped breast feeding, even though their own milk is richer in nutrients than the formula, and they do not have the sanitation necessary to keep the bottles and nipples clean. Consequently, malnutrition and infection have increased markedly among their babies.

Basch does not recommend any one plan for improving world health, "but it is essential to know the experiences of others, to extract and apply lessons from their successes, and to avoid the mistakes of their failures.

"International health is largely an extension of public health," says Basch, with the same goal as that of the local doctor—"improving the quality of life for individual human beings."

STANFORD—Stanford University Hospital has received full two-year accreditation by the Joint Commission on Accreditation of Hospitals (JCAH), according to Gary A. Mecklenburg, hospital administrator.

The accreditation is based on a survey completed in April by members of JCAH, the California Department of Health and the California Medical Association.

Two years is the maximum period of accreditation granted by JCAH.

Mecklenburg attributed the favorable survey findings to "significant achievements in providing a high standard of operation, and to an ongoing committment of the Hospital staff to deliver the highest quality of patient care.

"Patient services are of the highest quality, and the JCAH survey confirms that high standard."

The JCAH report outlined several recommendations and comments. Mecklenburg notes that many of these have already been addressed, or are in process.

JCAH is a nongovernmental organization operating under the auspices of the American College of Surgeons, the American Hospital Association, and the American Medical Association.

EDITORS: This release is issued jointly by the Stanford School of Medicine and by the Palo Alto Medical Clinic.

STANFORD—Stanford University School of Medicine and the Palo Alto Medical Clinic have formed a liaison committee to further mutual interests in medical care and education.

Formation of the new committee was announced today by Dr. Clayton Rich, dean of the School of Medicine and vice-president for medical affairs, and Dr. Robert Jamplis, director of the Palo Alto Medical Clinic.

Committee members include Drs. Jamplis, Hewlett Lee, George Janetos, Maurice Fox, and Sidney Hecker, of the Palo Alto Medical Clinic.

Members from Stanford include Dr. Rich, Dr. Lawrence Crowley, deputy dean of the School of Medicine; Dr. Irving Schulman, chairman of the department of pediatrics; Dr. Malcolm Bagshaw, chairman of radiology; and Dr. John Collins, chairman of the department of surgery.

The committee will be meeting at regular intervals to explore mutual areas of interest and concern.

A major area of common interest is how to strengthen the educational resources of the two institutions, and broaden the scope of the educational programs of the School for both medical students and postdoctoral trainees.

STANFORD—The applications of advanced technology to diagnosis and treatment of heart disease will be the subject of two international conferences held at Stanford University School of Medicine September 11-14, 1978.

The press is invited to attend sessions of the meeting on non-invasive cardiovascular measurements, September 11-12, and the fifth annual computers in cardiology conference, September 12-14. Both will be held in the Medical School's Fairchild Auditorium.

Workshops will focus on echocardiography, methods of blood flow detection, magnetocardiography, advances in computer tomographic (CT) scanning, nuclear imaging, computerized arrhythmia and intensive care monitoring, image processing and computer databases.

A training tutorial for physicians on computer interpretation of electrocardiograms (EKGs) will be given Monday, September 11.

Dr. C.A. Syvertson, new director of the National Aeronautics and Space Administration (NASA) Ames Research Center in Mountain View, California, will deliver the opening address of the first meeting on non-invasive cardiovascular measurements.

This conference, sponsored by NASA and Stanford's division of cardiology, represents the cooperative efforts of engineers and physicians at the two institutions in developing space-age technology for the diagnosis of heart disease.

The second conference, computers in cardiology, brings together scientists from 16 countries for a discussion of their work and interchange of ideas, according to Dr. Donald C. Harrison, director of the division of cardiology.

The computer conference is sponsored by the division of cardiology, the National Institutes of Health, and the Institute of Electrical and Electronics Engineers (IEEE).

Both meetings are open to the public, but require advance registration with the division of cardiology by Friday, August 11. Inquiries should be directed to Ms. Droni Moo, Stanford University School of Medicine, 701 Welch Road, Suite 3303, Palo Alto, CA 94304. She can be called at (415) 497-7507.

Press arrangements will be handled by the News Bureau. If you plan to cover or would like a program of the conferences, please return the form attached.

STANFORD—A clinic to treat alcoholics after they stop drinking is now underway at Stanford University Medical Center.

The emphasis of the clinic is to help the alcoholic and the person's family face long-term life problems, says Dr. Stephanie Brown, associate director of the program.

"We don't see ourselves as a replacement for Alcoholics Anonymous," she says. "In our group therapy the emphasis is on discussing concerns and worries...it is intensive psychotherapy and often the people who do best in these groups are people using other support programs such as AA."

The Stanford Alcohol Clinic is one of four specialty clinics within the Department of Psychiatry and Behavioral Sciences. These are the Couples and Family, Sleep Disorders and Stress Reduction clinics, in addition to the Alcohol Clinic.

The concept of these interacting clinics is unique, says Brown, because they recognize that patients often seek help for a complex web of problems.

This collaboration enables alcoholics to consult specialists about related problems such as anxiety, sleep disorders or marital conflicts.

"We are also interested in raising people's awareness of alcoholism...we need to legitimize the problem in our culture where drinking is the norm," Brown explains, adding that the wide acceptance of drinking as desirable social behavior means that overdrinking is often overlooked.

One of the challenges in treating alcohol-related problems, says Brown, is helping people acknowledge, initially, that drinking is a problem. "People are embarrassed--they think it is a weakness," she says.

There are also deeper inhibitions towards seeking treatment, she notes. "Many alcoholics are terrified of stopping drinking, although they recognize their self-destruction and want to stop."

Brown thinks adolescents need special attention.

"Adolescence is a time of transition when peer culture is very important," she says, stressing the usefulness of the clinic's group therapy techniques.

Another group which Brown would like to reach includes the adult children of alcoholics. She feels her program, with its focus on long-term problems , is especially suitable for dealing with the "emotional problems left over from growing up in a chaotic and inconsistent environment" with alcoholic parents.

The Alcohol Clinic sponsors a free education lecture series open to the public. The ten lectures will begin again in August, and Brown hopes to schedule an evening series in the fall.

STANFORD—The public's role in policy decisions concerning medical research and innovation is the subject of a project launched recently at Stanford University Medical Center.

The study is directed by Dr. Diana Dutton with Dr. John Bunker, and is funded by a three-year grant from the Ethics and Values in Science and Technology (EVIST) program of the National Science Foundation.

The researchers are currently seeking active participation in their study by interested citizens and public groups and will begin a series of workshops in the fall.

Dutton hopes that through the public's involvement, the study will gain a better perspective on problems in biomedical research policies and possible remedies.

Based in the Department of Family, Community and Preventive Medicine, the study also involves students and faculty from many disciplines including history, law, sociology, anthropology, philosophy, political science, economics and others.

The researchers will examine four controversial medical innovations:

* the national swine flu vaccination program
* DES(diethylsilbestrol) administered during pregnancy to prevent spontaneous abortion
* the artificial heart program
* recombinant DNA research

Bunker, who has written widely on the costs and benefits associated with surgical innovations, explains that often in the past, individuals have absorbed the costs which may accompany new technology. The study will explore other ways for society to absorb these costs and perhaps to avoid future unexpected adverse outcomes.

"More direct representation in decision-making of the individuals likely to suffer costs and risks might help to lessen these dangers," Dutton suggests.

The project conclusions will be published in articles and reports, and in a book for general readership.

STANFORD—Mary Catherine Krawec has been appointed to the new post of associate administrator for operational planning at Stanford University Hospital and Clinics.

According to Gary Mecklenburg, administrator of the Hospital and Clinics, Krawec will be responsible for coordinating and directing projects and programs to improve the operation of the Hospital and Clinics.

Her first project, Mecklenburg said, will be to plan additional Hospital operating rooms.

Krawec, who begins at her Stanford post Aug. 1, will also have specific responsibilities for the Health Services Planning Group.

In addition she will coordinate the Hospital program for continued compliance with the standards of the Joint Commission on Accreditation of Hospitals (JCAH), the California Health Department, California Medical Association, and other regulatory agencies.

Furthermore, Mecklenburg noted, Krawec will coordinate Stanford's involvement with appropriate health systems agencies.

Currently Krawec is director of regional operations of the New York City Health and Hospitals Corp., where she participated in developing and implementing the organization's emergency three-year fiscal plan.

She previously served as director of planning and as associate executive director at Greenpoint Hospital in Brooklyn.

Krawec is also a past assistant director at Bronx Municipal Hospital Center. She is a graduate of Catholic University in Washington, D.C., and holds a master's degree from Fairfield, CO, University.

STANFORD— Heart transplants may be done in 8 to 10 medical centers across the country within the next five years, predicts Dr. Edward B. Stinson, Stanford cardiovascular surgeon.

"Our record has encouraged a resurgence of serious interest by other centers," says Stinson.

Dr. Norman E. Shumway, who pioneered the transplant program at Stanford in 1968, says the surgery will remain "the ultimate therapeutic procedure" for patients with advanced heart disease who cannot be helped by other means.

The Stanford program has remained the only consistently active one in heart transplantation at the clinical level. Currently 146 patients have received new hearts at Stanford; 61 are now living.

Shumway cites steady improvement in survival rates, from 22 percent one-year survival in 1968 to 69 percent for current recipients. This success is comparable or superior to that attained in kidney transplants from unrelated donors, he says.

Recently, the School of Medicine was awarded a five-year federal grant for more that $5 million for continued clinical research.

The grant, funded by the National Heart, Lung, and Blood Institute, is the largest in the history of heart transplant research, according to NIH officials.

The funding will support the screening and selection of cardiac recipients, and hospitalization costs for the surgery and immediate postoperative period.

It will also support related research in pathology, transplantation biology, physiology, pharmacology, hematology, infectious disease, biomedical engineering and psychosocial studies.

Focus will be on immunological studies of transplant recipients before surgery, on ways to diagnose and treat rejection, on control of the body's immune response, and new ways to assess the capacity of the transplanted heart.

In addition to the clinical work, other research will examine the feasibility of a combined heart-lung transplant.

Heart transplant alone cannot be an alternative in many congenital heart problems, says Stinson, because of vascular and pulmonary impairment in addition to the heart problem.

-more-

Pilot studies of the combined heart-lung transplant are underway, he says, and work will begin soon in dogs. He foresees clinical application within 3-5 years.

Rejection remains the single most challenging problem of the transplant program. Immunosuppression has successfully prevented rejection in many patients, but leaves them susceptible to infections which can become life-threatening, says Stinson. The problem could be solved by an agent or technique which would make the body tolerant to the transplanted tissue without suppressing the body's defense to infection.

One research direction will be to study the control of immune response by use of total lymphoid irradiation before transplant. This form of radiotherapy has been used extensively to treat malignant lymphomas, such as Hodgkin's disease. Stinson terms the work "promising," and says study is underway in primates to evaluate its role as an immunosuppressive agent.

Researchers will continue to study and produce rabbit antithymocyte globulin (RATG), the immunosuppressive agent used for heart transplant patients since 1973. Studies have shown that rejection has been significantly less severe in those receiving RATG than in those who received equine antilymphocyte globulin.

Other Stanford laboratories are attempting to identify white blood cell factors which influence the acceptance or rejection of an organ transplant.

Histocompatibility (tissue typing) antigens, controlled by what is called the HLA system in man, are under study. There is some evidence that patients whose white cells mount a vigorous attack to a test panel in the laboratory may have more severe rejection episodes.

Unfortunately, says Stinson, simple matching of antigens of donor and recipient is not an answer to successful organ transplants, because so many other factors also govern rejection.

"There are no easy solutions to rejection," he says. "It will take careful, hard work, one step at a time."

Other research will examine the role of blood platelets and coagulation in transplantation, and recurrent, sometimes accelerated, coronary artery disease in longterm recipients.

- more -

Team members list development of the heart muscle biopsy technique as a key advance contributing to the success of the program. Essentially, a piece of wire with a clipper at the end is inserted into the patient's jugular vein and threaded down into the transplanted heart to obtain a small sample of the tissue. The sample can then be studied for early evidence of rejection or disease, enabling earlier treatment.

Another project is a broad analysis of the physiology and pharmacology of the transplanted heart, and its overall function.

Myocardial markers, tiny metal coils, made at the Palo Alto Medical Research Foundation, are implanted in the heart during surgery. With X-rays, physicians can then monitor changes in the heart over time.

They can also study the short-term recovery process after surgery, the effects of drugs and exercise, and the effects of the rejection process.

The renewed NIH grant also supports referral and evaluation of potential recipients, and their care while waiting for transplantation. Patient selection, says Stinson, has played an important role in assuring success.

Stanford receives more than 300 referrals a year for transplant, with 80 percent unable to meet the stringent measures of selection. Of the 20 percent evaluated at Stanford, 15 percent are accepted as candidates. Twelve percent of referrals survive to receive a transplant.

Besides the therapeutic and research aspects, Stinson describes the program as "an international demonstration project."

"One of our major goals is to refine the methodology so that others will not be doomed to failure, but have a chance for success they didn't have in 1968."

FOR FURTHER INFORMATION CONTACT: Bill Snyder 415: 497-6911

STANFORD— The Northern California Infant Medical Dispatch Center has been given $20,000 by the March of Dimes Foundation to support emergency transport of seriously ill infants.

Funding of the center by the State Department of Health expired June 30, and was not renewed pending examination of the impact of Proposition 13 on the state budget.

The center, located at Stanford University, coordinates intensive care resources of 10 hospitals in the 97,000 square mile region from the Oregon border to the Tehachipi Mountains.

A similar center, based at the University of Southern California, serves the southern part of the state. The centers were established in 1975.

"It is very important to get to the babies as quickly as possible," says Dr. Alvin Hackel, of the Northern California dispatch center.

"In the past, we've spent up to two hours finding an appropriate intensive care nursery to take them. We feel this extra time compromised the ultimate outcome of these patients," he says.

By coordinating intensive care nurseries, the dispatch centers reduced the search for empty beds to a matter of minutes.

According to Hackel, 120,000 infants were born in Northern California in 1977, and 2,200 required emergency transport. Of the requests for transport, 14 percent were handled by the dispatch center.

In addition to babies, the center transports pregnant women who are at high risk for complications during delivery. Last year, 65 women were transported to Stanford. That number has increased to 8-10 referrals each month, says Dr. Kent Ueland, professor of gynecology and obstetrics in the medical school.

Transports over 250 miles by air and surface ambulances are not uncommon.

A bill to provide funding for the infant transport program for one year is being considered by the state legislature. Sponsored by Assemblyman Leroy Greene (D-Sacramento), the bill would allocate $83,000 to the Northern California center, $95,000 to Southern California, and $75,000 for the development of a computerized data system.

The data system would speed the bed checking process even further, by keeping track of the number of available beds automatically. Presently, the center staff telephones hospitals with intensive care beds every eight hours, or more often in case of emergencies. In addition, the system would provide an efficient means of reviewing the effectiveness of the program.

Initially, the program was to have been given $540,000 for the next 18 months. As a result of the passage of Proposition 13, the funding was reduced to $253,000 for one year, as provided in the bill.

The bill presently is before the Senate Health Commmittee, and may not reach the floor of the Senate until sometime in August, according to Greene's office.

CITY DESKS: Transmitted by phone Friday, June 30, 1978.

STANFORD— Registered nurses at Stanford University Hospital represented by CRONA (Committee for the Recognition of Nursing Achievements) have reached final agreement on a new two-year contract with the hospital.

The agreement provides for a seven percent wage increase for the first year and an additional seven percent adjustment the following year.

In addition, it provides increased retirement benefits and educational opportunities such as specialty cross-training, educational grants and nursing licensure programs.

CRONA and the Hospital had engaged in collective bargaining since April 25. Tentative agreement was reached Thursday, and was ratified by an overwhelming majority of the nurses Friday, June 30.

In a joint statement the Hospital and CRONA negotiators described the contract as reflecting "a proper balance between the parties' desire to reward and support the excellent performance by the nurses and at the same time respond to concerns with health care costs."

CRONA said it was pleased with the course of negotiations and ultimate agreement and is anxious to take advantage of the Hospital's willingness to further open channels of communication between nurses and the hospital.

The hospital had received notice June 21 from CRONA indicating its intention to strike if an agreement was not reached by July 2.

However, once an early tentative settlement was reached, the notice was withdrawn.

Hospital officials praised the nurses for the manner in which they carried out their duties during the notice period and their offer to work with the hospital to care for critically ill patients in the event of a strike.

The hospital was represented by Joe Ross, associate director of Labor-Employee Relations, Priscilla Wheeler, Duane Walker, Carol Sasso, Carol Hoshour, and Susan Cabral.

CRONA was represented by Attorney Peter Fortune, and nurses Linda Simpson, CRONA president; Charlene Plourde, Barbara Duci, Joanna Nelson, and Marcie Singhaus.

STANFORD—University Hospital room rates will increase an average of $15-16 in the new fiscal year starting September 1.

The new rates, according to hospital administrator Gary Mecklenburg, reflect increased wages, utility costs, and the need to upgrade facilities.

Rates were approved by the University after the Hospital Board of Directors reviewed the annual budget on August 22, recommending rates for the new fiscal year.

Medical, surgical and gynecology room rates, which are charged to most hospitalized patients, will increase 9-10 percent from those set a year ago.

The new room rates will be $159 per day for ward accomodations, $172 for a semiprivate room, and $192 for a private room, up $15 from last year.

Patients utilizing medical, surgical and gynecology services of house staff physicians will pay $15 more than the above rates.

The level of rate increases will be approximately 12 percent for some specialized units, including the intensive and coronary care units and the nurseries.

Rate increases for psychiatry, obstetrics, and pediatrics will be similar to the average room rate increase of 10 percent.

Rates for X-ray, laboratory, and other ancillary services will be increased an average 13 percent.

The rate structure of the Emergency Department will be changed significantly, said Mecklenburg, by establishing several levels of charge depending on the severity of illness.

"For less serious illness and routine visits, Emergency Department charges will not increase and in some cases will actually decrease," he said.

In addition to meeting increased operating costs, the hike in patient charges is necessary to provide money for improving facilities and meeting code requirements, said Mecklenburg.

Over the next five years, additional funds may have to be raised or borrowed to meet expected capital needs, he said.

Full, two-year accreditation was granted the hospital by the Joint Commission on Accreditation of Hospitals this year, but further remodelling is required by the state Department of Health.

At the same time, the hospital has cut expenses in response to a reduction in patient census which is not completely offset by increases in the intensity of illness treated here, said Mecklenburg.

More than 98 percent of the hospital's funds, he said, come from patient revenues. The hospital has no tax support or endowment income.

STANFORD—The American Cancer Society announced Wednesday, Aug. 30, in New York that it plans to spend up to two million dollars for clinical testing to determine the possible value of human leukocyte interferon in the treatment of advanced cancer.

Dr. Thomas C. Merigan of Stanford University, a pioneer in interferon research, and Dr. Jordan Gutterman of the M.D. Anderson Hospital and Tumor Clinic of Houston, Texas will co-chair the scientific committee which will meet in New York next month to work out the details for the clinical trials.

"Interferon is a natural body substance which has been shown to reduce the size of tumors in animal experiments as well as in few scattered applications to human cancer patients," said an ACS statement. "Its ultimate usefulness against cancer has yet to be proved."

The ACS indicated that the society's involvement in interferon trials will be limited to purchase of the material, monitoring of the trials, and dissemination of the results.

Nearly all the world's supply of interferon is produced in Finland. Scarcity of the material probably will limit the trials to no more than 150 advanced cancer patients, the ACS said.

For scientific validity these will be randomly selected at institutions participating in the tests. These have not yet been selected.

Clinical testing with interferon has been done primarily in Sweden. At the Karolinska Institute in Stockholm, 34 patients—children and young adults—have survived osteogenic sarcoma after being treated with high doses of the substance.

The survival rate of these patients, according to the ACS, has been reported to be 70 percent over a period of three years, compared to normal expectations of 10 to 30 percent in patients treated by surgery alone.

In the United States 15 breast cancer patients have been treated with interferon at M.D. Anderson Hospital and Tumor Institute in Houston, and six lymphoma patients have been treated at Stanford University Medical Center.

Early indications suggest that interferon may have the capacity to bring about objective tumor reduction, said the ACS statement.

At Stanford, interferon also has been used successfully by Dr. Merigan and his associates to prevent in cancer patients the spread of herpes zoster, a virus which causes chicken pox and shingles. Such a virus infection is more frequent in cancer patients because their immune responses have been reduced by chemotherapy and radiation treatment.

Interferon occurs naturally in the body, and is believed to be non-toxic. It was first identified in 1957 by Alick Isaacs of Great Britain and Jean Lindenmann of Switzerland. They described it as a protein substance produced by a virus-infected animal cell, and observed that inteferon seemed to make surrounding cells resistent to infection by the same virus.

The substance is primarily species specific. That is, mouse interferon will work only in mice; human interferon will work only for humans. Interferon produced by one species will not work well or at all in another.

White blood cells are extracted from whole blood and exposed to a virus in order to produce human leukocyte interferon. The blood is obtained in procurement drives of the Finnish Red Cross, and processed by the Red Cross at laboratories in Helsinki.

'Interferon has not been synthesized nor has the gene for its production been isolated. Work is in progress in both areas.

STANFORD—Spinal fusion and a stiff neck are the characteristics of an enigmatic disease called ankylosing spondylitis, which may strike as many as three million Americans, according to researchers at the Stanford University Medical Center.

Most of the victims of this disease are undiagnosed and inadequately treated, say Drs. Andrei Calin and James F. Fries, who have recently published a review of the subject, entitled *Ankylosing Spondylitis—Discussions in Patient Management* (Medical Examination Publishing Co., Inc., NY, 117 pages, $10).

The disease usually appears in the early twenties, with chronic pain in the lower back. The discomfort is usually worse in the morning and improves with exercise. Over a period of years, the pain and accompanying stiffness may spread to the upper back, neck, hips and shoulders.

In advanced cases, the spine, neck and even the ribcage become inflexible. The disease may also involve the eye, aortic valve, lung and skin. Complications arising from these heart and lung disorders may lead to death.

The pain and stiffness of ankylosing spondylitis result from inflammation and progressive increases in fibrous tissue and bone in the spine, ribcage and joints. The symptoms may be relieved at any stage of the disease by postural exercises, anti-inflammatory medication, and, occasionally, radiation therapy.

However, "accurate early diagnosis and appropriate conservative clinical management do not prolong life and may not prevent later complications," say Calin and Fries.

The discovery of more effective therapies depends on a better understanding of the cause and mechanism of the disease, they say.

It is not known what causes ankylosing spondylitis, but it can be inherited. Ten percent of the immediate family (parents, siblings, offspring) of a patient with the disease are likely to have it.

The key to the disease seems to be a white blood cell marker or antigen known as HLA B27. Over 90 percent of persons afflicted with the disorder carry the B27 marker.
